ABSTRACT

Database Tomography (DT) is a textual database analysis system consisting of two major components: 1) algorithms for extracting multi-word phrase frequencies and phrase proximities (physical closeness of the multi-word technical phrases) from any type of large textual database, to augment 2) interpretative capabilities of the expert human analyst. DT was used to derive technical intelligence from an Nonlinear Dynamics database extracted from the combined Science Citation Index (SCI)/ Social Science Citation Index (SSCI), hereafter referred to as SCI. Phrase frequency analysis by the technical domain experts provided the pervasive technical themes of the Nonlinear Dynamics database, and the phrase proximity analysis provided the relationships among the pervasive technical themes. Bibliometric analysis of the Nonlinear Dynamics literature supplemented the DT results with author/ journal/ institution publication and citation data.

EXECUTIVE SUMMARY

ES-1. Overview

A text mining analysis of Nonlinear Dynamics was performed. The technical scope included that class of motions in deterministic physical and mathematical systems whose time evolution has a sensitive dependence on initial conditions.

An approximately 100 term query was developed for accessing records from the source SCI database. This query can be used periodically to update the currency of records retrieved.

The bibliometrics sections contained numerical indicators for each bibliometric examined, clustering results for most prolific authors and countries only, and highest frequency elements for each bibliometric. Four technical discipline taxonomies were generated: Keyword non-statistical, Abstract non-statistical, Abstract factor matrix statistical, Abstract multi-link clustering statistical.

ES-2. Bibliometrics

ES-2A. Prolific Authors

There were 6118 papers retrieved, 12136 different authors, and 16370 author listings. Table 2A lists the most prolific authors from 2001, and Table 2B lists the most prolific authors from 1991.

TABLE 2A – MOST PROLIFIC AUTHORS - 2001 (present institution listed)

Of the nineteen most prolific authors listed in Table 2A, six are from China. In fact, eight are from the Far East, four are from Western Europe, one is from Eastern Europe, five are from North America, and one is from South America. Seventeen are from universities, and two are from research institutes.

To determine the trends in this regional mix of prolific authors, the same query was applied to 1991 only. Table 2B lists the most prolific authors for 1991.

The regional mix of authors has some major differences from the 2001 results. Of the nineteen most prolific authors listed in Table 2B, <u>none</u> are from the Far East, eight are from the USA, nine are from Western Europe, and two are from Eastern Europe. Eighteen are from universities, and one is from a research institute.

Only two names were common to both lists, Ott and Grebogi. However, some researchers can have an off year for a number of reasons, so individual comparisons over two years, especially two widely separated years, may not be overly important. More important are country comparisons, and maybe institutional comparisons to some extent. These entities integrate over many individuals, and their performance would be more reflective of national policy. In this regard, the shift of prolific performers from the NATO countries in 1991 to those of the Far East in 2001 stands out.

Clusters of related authors were generated by two methods: factor matrix and multi-link aggregation. The 253 highest frequency authors were included. Co-author publishing groups were clearly identified, and fine-structure relationships within each group were clearly delineated. Based on name ethnicity alone, intra-country clustering appears to be the dominant form of grouping.

ES-2B. Prolific Journals

There were 1151 different journals represented, with an average of 11.90 papers per journal. The journals containing the most nonlinear dynamics papers (see Table 3A) had more than an order of magnitude more papers than the average.

The majority of the journals are physics, with the remainder divided between mathematics and electronics. Phys Rev E is the Physical Review journal assigned to chaos, while Phys Rev letters receives important papers for rapid publishing. Many (not all) of the other journals do not focus on nonlinear topics, but include papers in their specialties that also involve nonlinear aspects.

To determine the trends in journals containing the most nonlinear dynamics papers, the results from 1991 are examined. Table 3B contains the top twenty journals.

While the most prolific authors could be expected to change over a decade, for a number of reasons, the most prolific journals should be more stable. Comparison of Tables 3A and 3B shows this to be true. Of the nineteen most prolific journals, eleven are in common. For 2001, two journals were added devoted solely to chaos and closely related topics (CHAOS SOLITONS FRACTALS, INTERNATIONAL JOURNAL OF BIFURCATION AND CHAOS). Perhaps the largest change is the drop of Physical Review A from first in 1991 to twelfth in 2001, and the appearance of Physical Review E as first in 2001. Phys Rev E was split from Phys Rev A during the past decade, and received the Physical Review assignment for papers in chaos.

ES-2C. Prolific Institutions

The most prolific institutions from 2001 are listed in Table 4A, and the most prolific institutions from 1991 are listed in Table 4B.

TABLE 4A - PROLIFIC INSTITUTIONS - 2001

Of the thirty most prolific institutions, fourteen are from the USA, seven are from Western Europe, five are from Asia, two are from Eastern Europe, one is from Latin America, and one is from the Middle East. Twenty-five are universities, and the remaining institutions are research institutes. The most prolific institutions for nonlinear dynamics papers correlate well with institutions that have Centers for nonlinear dynamics.

To determine the trends in institutions containing the most nonlinear dynamics papers, the results from 1991 were examined. Table 4B contains the top thirty institutions.

TABLE 4B - PROLIFIC INSTITUTIONS - 1991

Of the thirty most prolific institutions in 1991, twenty are from the USA, five are from Western Europe, three are from Eastern Europe, one is from Asia, and one is from Canada. The major shift is substitution of Asian institutions for USA institutions.

ES-2D. Prolific Countries

There are 78 different countries listed in the results for 2001. The country bibliometric results are summarized in Table 5A and shown graphically in Figure 1. The dominance of a handful of countries is clearly evident.

TABLE 5A - PROLIFIC COUNTRIES - 2001

COUNTRY	# PAPERS

World Wide Non-Linear Dynamics Research (1991)

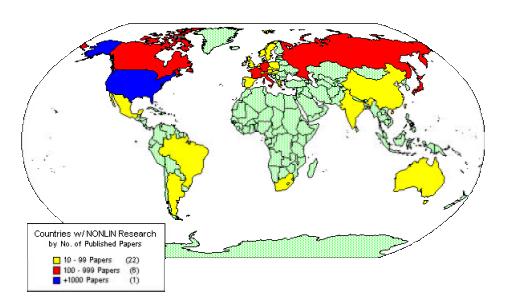

FIGURE 2 – COUNTRIES WITH THE MOST NONLINEAR DYNAMICS PAPERS – 1991

The major shift is the increased ranking of People's Republic of China from 11th in 1991 to 2nd in 2001, and the concomitant increase in numbers of papers from 63 to 584. To place China's increase in Nonlinear Dynamics papers in perspective, it is compared to China's overall increase in SCI papers from 1991 to 2001. In 1991, China had 8174 entries in the SCI, and in 2001, China had 36765 entries in the SCI. Thus, while China's papers in Nonlinear Dynamics in the SCI increased by a factor of ~9.25 from 1991 to 2001, China's overall increase in SCI papers from 1991 to 2001 was a factor of ~4.5. Thus, China's Nonlinear Dynamics papers outpaced its average growth of SCI papers by a factor of ~ 2.

Appendix 4 contains a co-occurrence matrix of the top 15 countries. In terms of absolute numbers of co-authored papers, the USA major partners are Germany, China, France, Canada, and England. Interestingly, the USA is China's dominant major partner, having four times the number of co-authored papers with China (72) as China's next larger partner, Canada (18). Overall, countries in similar geographical regions tend to co-publish substantially, the US being a moderate exception.

ES-2E. Most Cited Authors

The most highly cited authors are listed in Table 6.

CASATI G	UNIV INSUBRIA	ITALY	163

Of the twenty most <u>cited</u> authors, ten are from the USA, seven from Western Europe, one from Russia, one from Japan, and one from Latin America. This is a far different distribution from the most <u>prolific</u> authors of 2001, where eight of nineteen were from the Far East. This distribution of most cited authors more closely resembles the distribution of most prolific authors from 1991, where none were from the Far East. There are a number of potential reasons for this difference between most prolific and cited authors in 2001. The most prolific may not be the highest quality, or many of the most prolific authors could be relatively recent, and insufficient time has elapsed for their citations to accumulate. In another three or four years, when the papers from present-day authors have accumulated sufficient citations, firmer conclusions about quality can be drawn.

The lists of nineteen most prolific authors from 2001 and twenty most highly cited authors only had five names in common (OTT, NAYFEH, GASPARD, GREBOGI, LAI). This phenomenon of minimal intersection has been observed in all other text mining studies performed by the first author.

Fifteen of the authors' institutions are universities, four are government-sponsored research laboratories, and one is a private company.

The citation data for authors and journals represents citations generated only by the specific records extracted from the SCI database for this study. It does not represent all the citations received by the references in those records; these references in the database records could have been cited additionally by papers in other technical disciplines.

ES-2F. Most Cited Papers

The theme of each paper is shown in italics on the line after the paper listing. The order of paper listings is by number of citations by other papers in the extracted database analyzed. The total number of citations from the SCI paper listing, a more accurate measure of total impact, is shown in the last column on the right.

Physical Review Letters contains the most papers by far, four out of the twenty listed. Most of the journals are fundamental science journals, and most of the topics have a fundamental science theme. The majority of the papers are from the 1990s, with seven from the 1980s, one from the 1970s, and one extremely highly cited paper being from 1963. This reflects a dynamic research field, with seminal works being performed in the recent past.

Eight of the papers address issues related to chaos, with the dominant themes being conditions for determining chaos, and properties of strange attractors. Four of the papers address issues related to synchronization, with the focus on coupled chaotic oscillators.. Three of the papers address issues related to control, emphasizing self-controlling feedback. One paper addresses stability-related issues, focusing on

bifurcations, and one paper focuses on quantum chaos. There are three nonlinear dynamics books in the top twenty cited documents.

Thus, the major intellectual emphasis of cutting edge Nonlinear Dynamics research, as evidenced by the most cited papers, is well aligned with the intellectual heritage and performance emphasis, as will be evidenced by the clustering approaches.

ES-2G. Most Cited Journals

Table 8 lists the most highly cited journals.

TABLE 8 – MOST CITED JOURNALS (cited by other papers in this database only)

JOURNAL	TIMES
	CITED
PHYS REV LETT	10786
PHYS REV E	5310
PHYS REV A	3603
PHYSICA D	3579
PHYS LETT A	2308

ASTROPHYS J	1367
INT J BIFURCAT CHAOS	1279
SCIENCE	1256
PHYS REV D	1215
J PHYS A-MATH GEN	1073
PHYS FLUIDS	907
J ATMOS SCI	871
REV MOD PHYS	864
PHYS REP	813
J STAT PHYS	790
CHAOS	777

The first two groups of cited journals clearly stand out. PHYS REV LETT received almost as many cites as the three journals in the next group (PHYS REV E, PHYS REV A, PHYSICA D), or even the five journals in the following group (PHYS LETT A, J CHEM PHYS, J FLUID MECH, PHYS REV B, NATURE). PHYS REV LETT emphasizes rapid publication of 'hot' topics, and would therefore tend to establish primacy in an emerging field. Since one aspect of citations is identifying the original literature of a new topic, a credible journal with these characteristics would tend to receive large numbers of citations.

Unlike the relatively disjoint relationship between most prolific authors in 2001 and most cited authors, the relationship between most prolific journals in 2001 and most cited journals was much closer. Nine of the ten most highly cited journals were also on the list of twenty most prolific journals in 2001. The more applied journals on the most prolific list for 2001 are replaced by the more fundamental journals on the most cited list.

ES-3. Technical Discipline Taxonomies

ES-3A. Keywords Manual Taxonomy

All the Keywords from the extracted SCI records, and their associated frequencies of occurrence (with a threshold frequency of nine), were tabulated, and then grouped into categories by visual inspection. The phrases were of two types: applications-related and phenomena or tech-base-related. While the application sub-categories were relatively independent, there was substantial overlap between some of the tech-base categories. The detailed taxonomy results are presented in Appendix 5. Within each sub-category, thrust areas are presented in approximate frequency appearance order. These results are displayed in Table 9, and summarized now.

There are eight distinct applications categories, with four levels of stratification based on phrase frequency summations. Fluid Flow is the dominant stratification level, with the main emphasis being turbulence, convective transport, and diffusion. The second stratification level consists of Optics and Brain. The Optics emphases are lasers and associated nonlinear phenomena, while the Brain emphases are neural networks and analyses of broader neural system signals. The third stratification level consists of Environment and Cosmology. The Environment emphases are earthquakes and storms, while the Cosmology emphases center around evolution of the universe. The fourth stratification level consists of Materials, Chemistry, and Plasma (mostly fusion physics based). The Materials emphasis are split between solid mechanics/ structures issues and electronic properties/ applications issues.

There are fourteen tech base categories, also with four main stratification levels based on phrase frequency summations. The dominant level is Motion, consisting of the subcategories Evolution and Chaos. Evolution emphases are attractors and nonlinear dynamics. The second level consists of Stability, comprised of the sub-categories Stability and Maps. Stability emphases are bifurcations and the transitions to instability, while Maps emphasizes Poincare's surface intersections. The third level comprises Cycling and Modeling and Simulation, with Cycling further categorized into Oscillations, Periodicity, and Waves. Under Oscillations, nonlinear, chaotic, and coupled oscillators are emphasized, as well as limit cycles; under Periodicity, the focus is periodic orbits; and under Waves, the emphasis is traveling and solitary waves.

The fourth stratification level consists of Communication, Scaling, Thermodynamics, and Coupling. Communication comprises Signals and Circuits; Scaling comprises Quantum, Dimensionality, Localization, and Scaling; Thermodynamics comprises Entropy, Noise, Statistics, Dissipation, Thermodynamics, and Conservation; and Coupling comprises Synchronization and Resonance. Under Signals, time series

analysis and the associated intermittency are emphasized; under Quantum, small particle motions and interactions are emphasized; under Dimensionality, different measures of fractal dimensions of strange attractors are emphasized; under Entropy, patterns and pattern formation are emphasized; under Noise, brownian motion is emphasized; under Dissipation, hysteresis and friction are emphasized; and under Resonance, stochastic resonance is emphasized.

ES-3B. Abstracts Manual Taxonomy

A taxonomy of nonlinear dynamics applications and phenomena was developed through visual inspection of the TextDicer Abstract phrase frequencies. The developed taxonomy was subsequently used to approximate global levels of emphasis (GLE). This type of analysis would help identify adequately and inadequately supported system and subsystem tech base areas. It could also differentiate the developed and developing technology components of a particular system.

Table 10 contains the manual Abstract taxonomy.

Relative to the Keyword taxonomy, the Abstract taxonomies have two additional categories: Biology and Medical. While biological and medical terms can be found in the list of Keywords, they occur with a frequency lower than that used for cutoff. The reasons for this are unclear. In the Abstract phrase taxonomies, Biological and Medical are not the lowest frequency applications, and if the Keywords correlated with the Abstract phrases, one would expect Biology and Medicine to appear as Keyword taxonomy categories. It could be that: 1) the biomedical community uses a greater fraction of nonlinear dynamics phenomenological terms as Keywords than other application communities; 2) there is less agreement on medical terminology relative to other communities, and a greater variety of low frequency terms are used; or 3), a broader variety of medical sub-areas are being investigated with nonlinear dynamics than some of the other applications areas.

In addition, some new categories were generated for the Abstract taxonomies by fissioning categories in the Keywords taxonomy. For example, Optics in the Keywords taxonomy was split into Optics and Lasers for the Abstracts taxonomies, due to the

substantially greater amount of Abstract phrase detail, but it is fundamentally the same category.

Now, the emphasis areas of the Abstract phrase categories will be summarized.

Applications can be stratified into four main levels, based on summation of phrase frequencies as figure-of-merit. The dominant level consists of Fluid Flow (1025) and Optics (854), the latter including both Optical (506) and Laser (348). Fluid Flow emphasizes turbulence, vorticity, and convection; Optics emphasizes lasers and beams (generically electromagnetic beams, but usually laser or light beams).

The second level consists of Brain (606). Brain emphasizes neuron firings, EEG, epilepsy, and cortex.

The third level consists of Chemistry (359), Cosmology (353), Environment (404), and Material (481), the latter including both Materials (217) and Solid State (264). Chemistry emphasizes reaction and diffusion rates, combustion, catalysis, and Belousov-Zhabotinsky reaction; Cosmology emphasizes galaxies, black holes, and planets; Environment emphasizes atmosphere, weather (wind, climate, storms, rainfall), and ecology; Material emphasizes polymers, viscoelasticity, crystals, semiconductors, diodes, and tunneling.

The fourth major level consists of Medical (204), Geology (274), and Biology (246), Medical emphasizes cardiovascular problems (cardiovascular, blood pressure, fibrillation, heart rate, ventricular, pacemaker), and infectious disease (infection, virus).

Phenomena can be stratified into three main levels, based on summation of phrase frequencies as figure-of-merit. The dominant level consists of Stability (3854) and Cycling (3465). The Stability category can be divided into a Stability sub-category (3199) and a Maps sub-category (655). The Cycling category can be divided into an Oscillations sub-category (2106), a Periodicity sub-category (919), and a Wave sub-category (440).

Within the Stability category, the Stability sub-category emphasizes Hopf, pitchfork, period-doubling, global, saddle-node, homoclinic, local, transcritical, blowout, primary, and subcritical bifurcations, and bifurcation points/ diagrams/ curves/ structure/ control/ set/ buckling/ mechanism, stability and instability [LINEAR AND NONLINEAR STABILITY ANALYSIS, STABLE AND UNSTABLE PERIODIC ORBITS, ASYMPTOTIC STABILITY, ONSET OF INSTABILITY, UNSTABLE FIXED POINT(S), STABLE LIMIT CYCLE(S), UNSTABLE PERIODIC SOLUTIONS, CONDITIONS OF STABILITY, LINEAR STABILITY THEORY], Lyapunov criteria, and critical and equilibrium points; the Maps sub-category emphasizes Poincare, logistic, Henon, return, standard, circle, invertable and non-invertable, lkeda, unimodal, area-preserving, symplectic, and quadratic maps, center, invariant, stable and unstable, slow, compact, homoclinic, inertial, riemannian, Stiefel, and symplectic manifolds, and normal forms.

Within the Cycling category, the Oscillations sub-category emphasizes oscillators, vibrators, and limit cycles; the Periodicity sub-category emphasizes homoclinic, circular, chaotic, periodic, and quasi-periodic orbits, period doubling, and periodic points; the Wave sub-category emphasizes acoustic, gravity, nonlinear, solitary, spiral, standing, traveling, and water waves, wave equations, fronts, and packets, and wave forms and numbers.

The second level consists of Motion (2571), Scaling (2562), and Modeling and Simulation (1931). The Motion category can be divided into an Evolution sub-category (1218), a Chaos sub-category (554), and an Attractors sub-category (799). The Scaling category can be divided into a Quantum sub-category (1210), a Dimensionality sub-category (491), a Scaling sub-category (739), and a Localization sub-category (122).

Within the Motion category, the Evolution sub-category emphasizes dynamical systems, nonlinear dynamics, chaotic dynamics, time and nonlinear evolution, system and population dynamics; the Chaos sub-category emphasizes chaotic systems, motions, orbits, regimes, states, scattering, and trajectories, onset of chaos, transition to chaos, deterministic chaos, routes to chaos, and spatiotemporal chaos; the Attractors subcategory emphasizes chaotic, global, strange, coexisting, fixed point, periodic, great, hyperchaotic, multiple, random, stable, compact, and dynamical attractors, basins, attracting sets, attractor networks and dimensions.

Within the Scaling category, the Quantum sub-category emphasizes dynamics of small particles [ELECTRONS, IONS, ATOMS, MOLECULES, NUCLEI, PROTONS], lattices, quantum chaos/ dots/ dynamics/ interference/ mechanics/ states/ systems, the Schrodinger equations, and billiard models; the Dimensionality sub-category emphasizes correlation, fractal, embedding, Hausdorff, generalized, range, high and low, and finite dimensions, and degrees of freedom; the Scaling sub-category emphasizes fractals, time and length scales, and self-similarity; the Localization subcategory emphasizes dynamical, nonlinear, spatial, weak, Anderson, and electron localization, intrinsic localized modes, locally transversal linearization, localization length, localized states, and local linearization.

The Modeling and Simulation category emphasizes nonlinear, ordinary and partial differential, stochastic differential, delay differential, functional differential, difference, Navier-Stokes, reaction-diffusion, Fokker-Planck, constitutive, algebraic, Klein-Gordon, KDV, Burger, Euler, Boltzmann, Duffing, Lorenz, Mathieu, and Kuramoto-Sivashinsky equations, equations of motion, control, genetic, numerical, learning, backpropagation, decoding, and Grassberger-Procaccia algorithms, simulated annealing, numerical, computer, dynamical, model, nonlinear, direct, stochastic, monte carlo, and molecular dynamics simulations. and neural network, finite element, nonlinear dynamical, mathematical, numerical, linear and nonlinear, oscillator, chaotic, neuron, circuit, fuzzy, stochastic, mechanical, food chain, and general circulation models.

The third level consists of Communication (1530), Control (1361), Coupling (1375), Thermodynamics (1247), Structures (1100), and Experiment (1073). The

Communication category can be divided into a Signals sub-category (1081), a Circuits sub-category (220), a Communications sub-category (136), and a Code sub-category (61). The Coupling category can be divided into a Synchronicity sub-category (591), a Coupling sub-category (319), and a Resonance sub-category (465). The Thermodynamics category can be divided into a Noise sub-category (416), a Statistics sub-category (154), an Entropy sub-category (256), a Dissipation sub-category (303), and a Thermodynamics sub-category (118). The Structures category can be divided into a Nonlinear sub-category (678) and a States sub-category (422).

Within the Communication category, the Signals sub-category emphasizes chaotic, output and input, driving, control, beat, coupled, digital, error, external, microwave, nonlinear, and reference signals, time series, harmonic, anharmonic, and sub-harmonic, information and signal processing, and intermittency; the Circuits sub-category emphasizes electronic, chaotic, equivalent, nonlinear, shunt, and Pikovsky circuits; Josephson Junctions, and switches; the Communications sub-category emphasizes secure, chaotic, digital, and spread spectrum communications, and communication systems, communication channel the Code sub-category emphasizes coding and decoding, encryption, and security.

The Control category emphasizes feedback, delayed feedback, optimal, adaptive, nonlinear, chaos, robust, motion, tracking, active, mode, sliding mode, bifurcation, variable structure, and hybrid control, feedback, feed-forward, back-propagation, control system/ law/ strategy/ algorithm/ design/ theory.

Within the Coupling category, the Synchronicity sub-category emphasizes phase, chaos, generalized, global, asymptotic, lag, projective, and adaptive synchronization, phase, frequency, mode, and injection locking, discrete breathers, and synchronization error; the Coupling sub-category emphasizes coupled chaotic, coupled systems, coupling strength, strong coupling, weak coupling, and unidirectional coupling; and the Resonance sub-category emphasizes stochastic, internal, parametric, coherence, nonlinear, strong, size, primary, magnetic, cyclotron resonance, and resonance frequencies/ modes/ states.

Within the Thermodynamics category, the Noise sub-category emphasizes white, gaussian, external, additive, colored, measurement, random, dynamical, channel, correlated, stochastic, and thermal noise, and noise reduction/ intensity/ correlation/ amplitude/ sources, and Brownian Motion; the Statistics sub-category emphasizes Bose-Einstein, Bayesian, Ergodicity, Markov Chain, spectral, eigenvector, and Poisson statistics, and statistical properties/ mechanics/ ensembles/ distributions/ moments/ physics/ theory; the Dissipation sub-category emphasizes energy, tidal, numerical, artificial, and viscous dissipation, dissipative systems/ solitons/ structures/ dynamics/ models/ chaos/ maps, hysteresis; the Entropy sub-category emphasizes Kolmogorov, topological, approximate, information, Neumann, Shannon, linear, maximum, and Tsallis entropy, entropy production/ balance/ correlation/ fluctuations/ flux/ perturbations, spatial, wave, and spatiotemporal patterns, and pattern formation and recognition; the

Thermodynamics sub-category emphasizes thermodynamic limits and equilibrium, adiabatic approximation, and nonadiabatic systems and dust .

Within the Structures category, the Nonlinear sub-category emphasizes nonlinear systems/ interactions/ effects/ equations/ response/ terms/ regime/ phenomena/ function/ processes/ elastic/ prediction/ optimization/ stochastic/ viscoelastic/ dependence/ state/ boundary/ crystal/ structure; the States sub-category emphasizes ground, coherent, equilibrium, bound, stationary, excited, transition, basic, system, quiescent, rest and turbulent states, and state variables/ estimation/ vectors.

The Experiment category emphasizes experimental results/ data/ observations/ measurements/ evidence/ conditions/ models/ verification/ techniques/ apparatus/ device/ dynamics, numerical, laboratory, computer, simulation, independent, and physical experiments, electric, magnetic, and electromagnetic fields, MEMS, microscopy, and spectroscopy,

The remaining categories are small, and will not be discussed further.

ES-3C. Abstract Factor Matrix Taxonomy

The highest frequency high technical content phrases, with record frequencies not below seven, were identified (640 phrases). Very similar phrases were consolidated (e.g., singulars/ plurals, full spellings/ acronyms, strong synonyms), as shown by the process in Appendix 7. A correlation matrix of the 253 resultant consolidated phrases was generated, and a factor analysis was performed using the WINSTAT statistical package. The eigenvalue floor was set equal to unity, and a factor matrix consisting of 20 factors resulted. A description of each factor, and their aggregation into a taxonomy, follows. The capitalized phrases in parentheses represent typical high factor loading phrases for the factor described. Typically, the first few phrases presented dominate the themes. The complete factor matrix is presented in Appendix 8.

Factor 1 (BIFURCATIONS, STABILITY, POINCARE MAPS, PERIODIC MOTIONS, PERIODIC SOLUTIONS, PHASE PLANE, LIMIT CYCLES, PHASE PORTRAITS, FIXED POINTS, PERIOD DOUBLING, EQUILIBRIUM POINTS, also including LYAPUNOV EXPONENTS, NORMAL FORMS, FLOQUET THEORY) – focuses on stability of periodic systems, emphasizing onset and prediction of instabilities. Examines routes to chaos through bifurcation and associated period doubling, using reduced and normal forms of the Poincare map, as well as phase plane trajectories to plot the motions.

Factor 2 (CLASSICAL SYSTEM, CLASSICAL LIMIT, QUANTUM SYSTEMS, QUANTUM DYNAMICS, TRACE FORMULA, QUANTUM MECHANICS, TIME EVOLUTION, CLASSICAL DYNAMICS, DYNAMICAL EVOLUTION, BROWNIAN MOTION, also including QUANTUM-CLASSICAL CORRESPONDENCE, DECOHERENCE, COHERENT STATES) — focuses on correspondence between quantum dynamical systems and classical systems, especially focusing on the classical

limit behavior of quantum systems, as well as the trace formula's semiclassical representation for a quantum system's density of states in terms of the periodic orbits of the underlying classical dynamics.

Factor 3 (RANDOM MATRIX THEORY, ENERGY LEVELS, SPECTRAL STATISTICS, STATISTICAL PROPERTIES, EIGENFUNCTIONS, QUANTUM-CLASSICAL CORRESPONDENCE, ERGODICITY, WAVE FUNCTIONS, also including CHAOS, PERIODIC ORBITS, QUANTUM DOTS) – focuses on potential links between the statistical distribution of the energy levels of classically chaotic systems and the eigenvalue correlations of random matrix theory, or between the quantum properties of individual deterministically chaotic systems and of ensembles of randomly disordered systems.

Factor 4 (BASINS, ATTRACTORS, INVARIANT SUBSPACE, COUPLED CHAOTIC SYSTEMS, INTERMITTENCY, SYMMETRY BREAKING, MANIFOLDS, also including FRACTALS, SCALING, INVARIANT SETS, GLOBAL DYNAMICS, BIFURCATIONS, PHASE PLANE) – focuses on formation of riddled basins (every point in a chaotic attractor's basin has pieces of another attractor's basin arbitrarily nearby) and off-on intermittency by the loss of transverse stability of an invariant subspace containing a chaotic attractor; examines the effect of perturbation-induced symmetry-breaking on blowout-bifurcations (accompanying Lyapunov exponent sign reversal) that create riddled basins.

Factor 5 (SYNCHRONIZED, FREQUENCY DETUNING, FEEDBACK, COUPLING, LASERS, NOISE, GENERALIZED SYNCHRONIZATION, PHASE LOCKING, COHERENCE RESONANCE, DRIVE SYSTEM, CHUA'S C'RCUIT, LORENZ SYSTEM, INFORMATION SIGNAL, CHAOTIC DYNAMICAL SYSTEMS, also including WEAKLY NONLINEAR ANALYSIS, PATTERN FORMATION, CHAOS, NEURAL NETWORKS, NEURONS, OSCILLATORS) – focuses on synchronization of chaotic dynamical systems, especially optically coupled diode lasers with optical feedback, and examines synchronization robustness with respect to frequency detuning.

Factor 6 (LYAPUNOV EXPONENTS, POWER SPECTRUM, CORRELATION DIMENSIONS, TIME SERIES, KOLMOGOROV ENTROPY, FRACTALS, HEART RATE, SPECTRAL ANALYSIS, CIRCULAR ORBIT, also including ATTRACTORS, INTERMITTENCY, NOISE, CHAOS, POWER LAW, FREQUENCY DOMAIN, TIME DOMAIN, SYSTEM DYNAMICS, POINCARE MAPS, PHASE PLANE, PHASE PORTRAITS) – focuses on application of chaos metrics/ tools (Lyapunov exponents, power spectra, correlation dimension, fractals) to time series, especially from heart and brain wave generators, to fully characterize the nonlinear dynamical components of the signal.

Factor 7 (SCALING, MODULATION EQUATIONS, NORMAL FORMS, PARAMETRIC EXCITATION, LINEAR ANALYSIS, LAGRANGIAN, HOMOCLINIC, FLOQUET THEORY, also including BIFURCATIONS, STABILITY, LIMIT CYCLES, PERIOD DOUBLING, INTERMITTENCY, HOMOCLINIC ORBITS, DUFFING OSCILLATOR) –

focuses on use of multiple scales to derive modulation equations (mainly Ginzburg-Landau equations expressing time variation of amplitude and phase), in standard normal form of low co-dimension bifurcations.

Factor 8 (VISCOSITY, WEAKLY NONLINEAR ANALYSIS, FLUID DYNAMICS, SURFACE TENSION, REYNOLDS NUMBERS, ANGULAR VELOCITY, GLOBAL EXISTENCE, PATTERN FORMATION, FREE SURFACE, STEADY-STATE, SHEAR, also including STABILITY, FREQUENCY DETUNING, AMPLITUDE EQUATIONS, FREQUENCY DOMAIN, TIME DOMAIN,) – focuses on dynamics of fluids where viscosity and surface tension are important (fluid-fluid and fluid-surface interactions, as well as some cases of free-surfaces). Examines stability and pattern formation as functions of different dimensionless parameters (Reynolds Numbers, Weber Number, Bond Number).

Factor 9 (CHAOS, NEURAL NETWORKS, NEURONS, MAPS, COMPLEX SYSTEMS, also including POINCARE MAPS, LIMIT CYCLES, TIME EVOLUTION, STATISTICAL PROPERTIES, ATTRACTORS, SYNCHRONIZED, LORENZ SYSTEM, LYAPUNOV EXPONENTS, CONTROLS, PHASE SPACE, INITIAL CONDITIONS, CHAOTIC DYNAMICS, STATE SPACE, LOCAL DYNAMICS) – focuses on nonlinear dynamics of coupled neurons in complex networks, emphasizing the use of coupled maps exhibiting chaotic oscillations to simulate the network behavior.

Factor 10 (ANGULAR MOMENTUM, TOTAL ENERGY, POWER LAW, NATURAL FREQUENCY, LOCAL MINIMA, FLUCTUATIONS, VORTICITY, also including CLASSICAL SYSTEM, TRACE FORMULA, STATISTICAL PROPERTIES, QUANTUM-CLASSICAL CORRESPONDENCE, TOPOLOGY) – focuses on major integrals of motion of interacting systems described by power law distribution spectra, especially in the transition regime between integrability and chaos.

Factor (EXTERNAL DISTURBANCES. CONTROLS. **PARAMETRIC** UNCERTAINCIES, SYSTEM RESPONSE, FRICTION, NONLINEAR DYNAMICAL SYSTEMS, MECHANICAL SYSTEMS, DYNAMIC RESPONSE, OPTIMAL CONTROL, NONLINEARITY, CLOSED-LOOP SYSTEM, CONSTANT VELOCITY, RELATIVE MOTION. **DYNAMIC** PROPERTIES, also includina MODELS. SYSTEM PARAMETERS, NEURAL NETWORKS) - focuses on adaptive robust control of nonlinear dynamical systems subject to external disturbances and parametric uncertainties, with emphasis on mechanical systems such as robots and automobiles.

Factor 12 (HOMOCLINIC ORBITS, PERIODIC ORBITS, TOPOLOGY, PHASE SPACE, SCALAR FIELD, HAMILTONIAN SYSTEMS, CRITICAL POINTS, INITIAL CONDITIONS, ANISOTROPY, VECTOR FIELDS, SINGULARITY, INVARIANT SETS, CHAOTIC DYNAMICS, DUFFING OSCILLATOR, also including POINCARE MAPS, PHASE PLANE, ATTRACTORS, NORMAL FORMS, HOMOCLINIC, MAPS, SYSTEM DYNAMICS) – focuses on orbits for which the stable and unstable manifolds intersect, especially those accompanied at small values of the bifurcation parameter by the

existence of a countable set of periodic and an uncountable set of aperiodic solutions (i.e., chaotic structure) in the proximity of the homoclinic.

Factor 13 (DIFFUSION COEFFICIENT, HAUSDORFF DIMENSION, EQUILIBRIUM STATE, RELAXATION, COMPLEX PLANE, LONG-TIME BEHAVIOUR, FIELD LINES, TIME DEPENDENCE, also including EIGENFUNCTIONS, LYAPUNOV EXPONENTS, FRACTALS) – focuses on relations between transport coefficients and chaotic properties for systems relaxing to equilibrium, emphasizing the relation between the diffusion coefficient and the fractality (the Hausdorff Dimension and the Lyapunov exponent) of the hydrodynamic modes of transport.

Factor 14 (EXPONENTIAL DECAY, DECOHERENCE, TOPOLOGICAL ENTROPY, COHERENT STATES, CLOSED ORBITS, ESSENTIAL SPECTRUM, AMPLITUDE EQUATIONS, CONVERGENCE PROPERTIES, PROBABILITY DISTRIBUTIONS, PHASE TRANSITION, also including CLASSICAL SYSTEM, EIGENFUNCTIONS, MUTUAL INFORMATION) — focuses on decoherence effects of environment and detectors on quantum systems, whose classical correspondents are chaotic, and relates the decay function of the decoherence effect to the purely exponential decay characteristic of chaotic motion.

Factor 15 (ENTROPY, MUTUAL INFORMATION, THERMODYNAMICS, SPEECH, LONG TIME, POPULATION DYNAMICS, CORRELATION FUNCTION, also including QUANTUM MECHANICS, CLASSICAL DYNAMICS, LYAPUNOV EXPONENTS, CORRELATION DIMENSIONS, MAPS, TOPOLOGICAL ENTROPY, QUANTUM DOTS) – focuses on the use of mutual information between random variables and information theory analogues of thermodynamic entropy to analyze system dynamics and time series, in order to indicate structure or correlation and quantify informatioon content.

Factor 16 (FREQUENCY DOMAIN, TIME DOMAIN, DIFFERENTIAL EQUATIONS, FOURIER, SYSTEM DYNAMICS, ASYMPTOTIC EXPANSION, LINEAR SYSTEMS, REAL TIME, PERIODICITY, STATE SPACE, DIFFERENCE EQUATIONS, also including LIMIT CYCLES, FIXED POINTS, COMPLEX BEHAVIOR, TRACE FORMULA, TIME SERIES, CONTROLS, CONVERGENCE PROPERTIES) – focuses on control of limit cycle oscillations in dynamical systems, emphasizing time series analyses (e.g., convolutions) in the time domain, then Fourier transforms of time series into frequency domain, and subsequent frequency domain analyses.

Thus, the 16 factors can be viewed as thrust areas constituting the lowest level taxonomy. Each factor contains one or more of the following elements: 1) Sub-system –specific (e.g., neurons); 2) System-specific (e.g., brain); 3) System-generic (e.g., biological systems); 4) Phenomenon (e.g., bifurcations). Thus, there are myriad ways to combine the factors, depending on which dominant characteristics are chosen. In practice, the aggregation methodology will depend on the application for the taxonomy. For example, if the taxonomy is used to identify participants for a comprehensive workshop on Nonlinear Dynamics sources, categorizing by phenomena would identify

e.g., mapping experts, while categorizing by system would identify e.g. laser experts. Selection of aggregation attributes would depend on the workshop objectives. Conversely, assume the taxonomy is used by a program manager to estimate global levels of effort in specific technologies, in order to identify technology areas of adequacy and deficiency. Then, categorizing by phenomena would identify e.g., mapping deficiencies, whereas categorizing by system would identify e.g., laser deficiencies.

The factors above were aggregated by phenomena, using the higher level categorical structuring described in the next section. The following hierarchical level taxonomy resulted (numbers in parenthesis are factor numbers from above).

The highest level taxonomy consists of:

IA-Chaotic Motion

IB-Nonlinear Systems Concepts not necessarily linked to Chaotic Motion

The next highest level taxonomy consists of:

IA1-Characteristics and analysis tools for chaotic systems (1, 3, 4, 6, 12, 13)

IA2-Synchronization and control of coupled systems (5, 9)

1B1-Analytic tools for nonlinear analysis of specific applications (8, 11)

IB2-Methods to simplify solutions of high dimensional nonlinear equations (2, 7, 10, 14, 15, 16)

ES-3D. Abstract Multi-Link Clustering Taxonomy

A symmetrical co-occurrence matrix of the 253 highest frequency high technical content phrases was generated. The matrix elements were normalized using the Equivalence Index (Eij=Cij^2/Ci*Cj, where Ci is the total occurrence frequency of the ith phrase, and Cj is the total occurrence frequency of the jth phrase, for the matrix element ij), and a multi-link clustering analysis was performed using the WINSTAT statistical package. The Average Linkage method was used. Three types of raw data output were generated by each clustering run: a dendogram, a table, and a taxonomy. These three types of data output are described in detail in Appendix 1. The final 253 phrase dendogram is shown in Appendix 8. A description of the final dendogram, and the aggregation of its branches into a taxonomy of categories, follows. The capitalized phrases in parentheses represent cluster boundary phrases for each category.

The 253 phrases in the dendogram are grouped into 26 clusters. These clusters form the lowest level of the taxonomy hierarchy. Each cluster is assigned a letter, ranging from A to Z. The cluster hierarchies are determined by the branch structure. Overall, there are two main branches (clusters). Starting from the phrase adjoining the 'distance' ordinate, the first main cluster (A-M) ranges from MODELS to COMPLEX SYSTEMS. The second main cluster (N-Z) ranges from NONLINEAR PHENOMENA to TIME INTERVALS. While the total dendogram reflects different aspects of nonlinear dynamics, the first cluster (A-M) covers different aspects of chaotic motion, while the second cluster (N-Z) covers nonlinear system concepts with no specified links to chaotic motion. Each of these large clusters will be divided and sub-divided into smaller clusters, and discussed.

Cluster (A-M) can be divided into clusters (A-I) and (J-M). Cluster (A-I) ranges from MODELS to LINEAR SYSTEMS, and cluster (J-M) ranges from OSCILLATORS to COMPLEX SYSTEMS. Cluster (A-I) focuses on general characteristics of, and tools used to analyze, chaotic systems, while cluster (J-M) focuses on the synchronization and control of coupled systems subject to noise and other external disturbances.

Cluster (N-Z) can be divided into clusters (N-V) and (W-Z). Cluster (N-V) ranges from NONLINEAR PHENOMENA to CHAOTIC INFLATION, and cluster (W-Z) ranges from PERIODIC ORBITS to TIME INTERVALS. Cluster (N-V) focuses on the use of analytical tools (Fokker-Plank equation, Galerkin method, finite element method) for the nonlinear analysis of specific applications (aircraft vorticity, earthquakes, fluid dynamics, speech), and cluster (W-Z) focuses on methods to simplify solutions of high dimensional nonlinear equations (e.g., correspondence of quantum and classical systems, power law approximations, time domain-frequency domain transforms).

Cluster (A-I) can be subdivided into clusters (A-F) and (G-I) Cluster (A-F) ranges from MODELS to SCALAR FIELD, and focuses on analysis tools for, and characteristics of, chaotic systems. Cluster (G-I) ranges from MAPS to LINEAR SYSTEMS, and incorporates phenomena associated with chaotic and non-chaotic systems. Each of these clusters can now be divided into its elemental clusters.

Cluater A (MODELS to LAGRANGIAN) focuses on stability of periodic systems, emphasizing onset and prediction of instabilities; models periodic motions of dynamic systems to identify bifurcations that alter the stability of fixed points into limit cycles; uses multiple scales to derive modulation equations (mainly Ginzburg-Landau equations expressing time variation of amplitude and phase), in standard normal form of low codimension bifurcations.

Cluster B (PERIODIC SOLUTIONS to CONTINUATION METHOD) focuses on stability analysis and routes to chaos, using bifurcation diagrams, reduced and normal forms of the Poincare map, phase portraits, as well as phase plane trajectories to plot the motions.

Cluster C (HOMOCLINIC ORBITS to CIRCULAR ORBITS) focuses on periodic solutions near the homoclinic orbit of the Duffing oscillator with small perturbations, and on the conditions under which chaotic orbits can occur.

Cluster D (CHAOS to MODULATION FREQUENCY) focuses on application of chaos metrics/ tools (Lyapunov exponents, power spectra, correlation dimension, fractals) to time series, especially from heart and brain wave generators, to fully characterize the nonlinear dynamical components of the signal.

Cluster E (ATTRACTORS to COUPLED CHAOTIC SYSTEMS) focuses on formation of riddled basins (every point in a chaotic attractor's basin has pieces of another attractor's basin arbitrarily nearby) and off-on intermittency by the loss of transverse stability of an invariant subspace containing a chaotic attractor; examines the effect of perturbation-induced symmetry-breaking on blowout-bifurcations (accompanying Lyapunov exponent sign reversal) that create riddled basins.

Cluster F (INITIAL CONDITIONS to SCALAR FIELD) focuses on system dynamical evolutions based on initial conditions, and examines the topology of local and global dynamics in the phase space.

Cluster G (MAPS to DYNAMICAL EVOLUTION) focuses on chaotic maps with an invariant measure, the conditions under which period doubling is present on the route to chaos, and the fractality of the chaotic attractor.

Cluster H (DYNAMIC PROPERTIES to STOCHASTIC) focuses on dynamic properties of periodic orbits and chaotic attractors, and includes the use of maps to allow calculations of the location and stabilities of the periodic points in the chaotic attractor.

Cluster I (DIFFERENTIAL EQUATIONS to LINEAR SYSTEMS) focuses on the equations used to describe dynamical systems, and on the parameter-dependent periodic windows in the chaotic motions in which non-chaotic motion may be found.

Cluster (J-M) can be divided into its elemental clusters.

Cluster J (OSCILLATORS to INFORMATION SIGNAL) focuses on synchronization of chaotic dynamical systems, especially optically coupled diode lasers with optical feedback, and examines synchronization robustness with respect to frequency detuning.

Cluster K (SYSTEM DYNAMICS to DETERMINISTIC DYNAMICS) focuses on dynamics of chaotic systems (especially biological) in the presence of noise, including noise-enhanced temporal regularity, leading to determination of the vector field of the chaotic dynamics.

Cluster L (CONTROLS to THEORETICAL MODEL) focuses on adaptive robust control of nonlinear dynamical systems subject to external disturbances and parametric uncertainties, with emphasis on mechanical systems such as robots and automobiles.

Cluster M (NEURAL NETWORKS to COMPLEX SYSTEMS) focuses on use of neural networks to simulate brain subsystems, and the impact of both neuron models and temporal and spatial correlations in neuronal activity on the simulation strength of the neural network.

Cluster (N-V) may be divided into its elemental clusters, and cluster (W-Z) may be divided into its elemental clusters.

Cluster N (NONLINEAR PHENOMENA to ENERGY TRANSFER) focuses on nonlinear phenomena in aircraft flight, such as limit cycle oscillations, and the role of flow-field vortices in these fluid-structure oscillatory phenomena.

Cluster O (QUASIPERIODIC to NORMAL MODES) focuses on solving for velocity distributions and other variables of continuum flows in bounded regions with surface friction, using the Galerkin integral approach to solve the equations; solving for velocity distributions and other variables of particle flows in unbounded regions with interparticle friction, using the Fokker-Planck kinetic equations to solve the equations; solving for structural dynamic responses to relative motions induced by to earthquakes, using finite element techniques.

Cluster P (FLUID DYNAMICS to ESSENTIAL SPECTRUM) focuses on fluid dynamics of partially or fully unbounded flows at different Reynold's Numbers, where surface tension at the free surface tends to increase instabilities and the fluid viscosity tends to reduce instabilities; population dynamics (mainly smaller animal species), emphasizing self-organization and pattern formation.

Cluster Q (IONS to MULTIPLE SOLUTIONS) focuses on quantum dots (semiconductor nanoparticles) and their structural and interaction similarities to large molecules and ions; the use of mutual information between random variables and information theory analogues of thermodynamic entropy to analyze system dynamics and time series, in order to indicate structure or correlation and quantify information content.

Cluster R (CALCULATIONS to NONLINEAR EQUATIONS) focuses on flows in heated channels, and the onset of instabilities as a function of channel aspect ratio and Rayleigh Number.

Cluster S (MAGNETIC FIELDS to LONG-TIME BEHAVIOR) focuses on transport coefficients across and parallel to ambient magnetic field lines in turbulent flows, both in space and fusion-driven plasmas; dissipative fluid flow systems, with turbulent kinetic energy and shear; relations between transport coefficients and chaotic properties for systems relaxing to stationary states, emphasizing the relation between the diffusion

coefficient and the fractality (the Hausdorff Dimension and the Lyapunov exponent) of the hydrodynamic modes of diffusion.

Cluster T (STEADY STATE to SPATIAL DISTRIBUTION) focuses on steady-state CO oxidation over Pd or Pt catalysts, including regular, chaotic, or mixed mode reaction rate oscillations driven by mass transfer limitations or external parameter variations.

Cluster U (RESONANCES to CONSTITUTIVE EQUATIONS) focuses on linear approximations to constitutive rheological equations to study temporal evolution of stress and other interface phenomena, emphasizing interface phenomena resonances as a function of parameter variations.

Cluster V (GROUND STATE to CHAOTIC INFLATION) focuses on changes in ordering of layers of molecule-sized particles, as a function of temperature and film thickness; chaotic conditions for chaotic nature of radiation emitted from black hole candidates, and energy spectra of this radiation.

Cluster W (PERIODIC ORBITS to TOTAL ENERGY) focuses on trace formulas, which in general relate the density of states for a given quantum mechanical system to the properties of the periodic orbits of its classical counterpart (quantum-classical correspondence); potential links between the statistical distribution of the energy levels of classically chaotic systems and the eigenvalue correlations of random matrix theory, or between the quantum properties of individual deterministically chaotic systems and of ensembles of randomly disordered systems; major integrals of motion of interacting systems described by power law distribution spectra, especially in the transition regime between integrability and chaos.

Cluster X (BOUNDARY CONDITIONS to DECOHERENCE) focuses on the influence of boundary conditions on the evolution of coherent structures in pattern formation, using the Ginzburg-Landau form of the amplitude equations.

Cluster Y (TIME DOMAIN to OPTIMAL CONTROL) focuses on control of limit cycle oscillations in dynamical systems, emphasizing time series analyses (e.g., convolutions) in the time domain, then Fourier transforms of time series into frequency domain, and subsequent frequency domain analyses; also establishes optimal control conditions for pertubed systems using ergodicity assumptions.

Cluster Z (SYMBOLIC DYNAMICS to TIME INTERVALS) focuses on decoherence effects of environment and detectors on quantum systems, whose classical correspondents are chaotic, and relates the decay function of the decoherence effect to the purely exponential decay characteristic of chaotic motion; use of topological methods to support symbolic dynamics, show existence of closed orbits, and estimate topological entropy.

ES-4. USA/ China Technical Emphasis Comparison.

The bibliometrics results showed that China's ranking as a prolific producer of nonlinear dynamics' research papers increased substantially over the past decade. It might be useful to identify their technology focus areas. In particular, it would be interesting to identify some technology areas in nonlinear dynamics in which the U. S. is a major player and China a minor player, and vice versa.

A non-symmetric Abstract phrase-country matrix was generated using the Abstract phrases and countries generated by the ACCESS template. All the countries were included, and Abstract phrases with a frequency of three or greater were included. The matrix elements' values reflected the number of records in which Abstract phrase x co-occurred with country y.

Only the columns for China and the USA were analyzed. The raw data phrases in the China column were normalized (multiplied by approximately three), such that the total number of China's 2001 records was set equal to the total number of USA 2001 records. The phrases in these two columns were compared, and the ratio of record frequencies for China's phrases to those of the USA was used as a comparison metric. This ratio ranged from infinity (finite occurrences in the China column, zero occurrences in the USA column) to zero (zero occurrences in the China column, finite occurrences in the USA column. The number of phrases in the different bands of the comparison metric is shown in Table 11.

TABLE 11 – RATIO OF RECORDS WITH SELECTED PHRASES IN NONLINEAR DYNAMICS CHINA/ USA LITERATURE – 2001

METRIC BAND	# PHRASES			
INFINITY	1238			
9 TO 25	138			
.11 TO 9	7057			
.05 TO .11	34			
0	10686			

There were a total of 19153 candidate phrases. For the present purpose of identifying major asymmetries, only the phrases with very high or very low record frequency ratios (the wings of the distribution function) were examined. Of this subset, only the phrases above a threshold of record frequencies were considered.

Table 12 contains phrases that met the numeric criteria (above), appeared to be significant technically, and, for the USA-predominant phrases in particular, appeared to be part of a pattern.

TABLE 12 – PHRASES WITH VERY HIGH OR LOW CHINA/ USA RECORD FREQUENCY RATIOS

PHRASE	RAW-	USA	NORM	CH/ US
NATIONAL ENTERNIAL	DATA		0.47	13.15

ANGLE OF ATTACK	0	5	0	0
INTERSTELLAR	0	5	0	0
GALAXY	0	5	0	0

In Table 12, the leftmost column is the phrase of interest, the next column is number of China records in which the phrase appears, the next column is number of USA columns in which the phrase appears, the next column is the normalized China column, and the rightmost column is the ratio of the normalized China column matrix element to the USA column matrix element. The distribution in Table 12, as well as in the raw data, is asymmetric. There are many more phrases that appear predominately in USA records than predominately in China records.

The first six phrases in Table 12 are those that predominate in China records. The only pattern appears to focus on noise. While the phrase NOISE is about equally distributed between China and USA records in the raw data, some variants predominated in the China records, as shown in Table 12.

The remainder of the phrases in Table 12 are those that predominate in USA records. Perhaps the most surprising is MAGNETIC FIELD(S). For the 2001 database, there are 64 USA records that contained MAGNETIC FIELD(S), and no China records. A sampling of these USA records showed them to be of two generic types. The dominant type addressed the nonlinear dynamics of magnetic fields in space plasmas, and the other type addressed the nonlinear dynamics of magnetic fields in controlled magnetic fusion systems. These applications areas require large experimental and flight facilities to conduct research and obtain data. The USA has large efforts in both areas, whereas China has minimal efforts in both. Other USA-dominant phrases from Table 12 related to space research support this reasoning (SOLAR, GALAXIES, STELLAR, BLACK TROPOSPHERE, GALACTIC, TELESCOPE, ASTROPHYSICAL, HOLE(S), INTERSTELLAR, GALAXY).

Two major caveats on the data in Table 12 should be emphasized. First, only phrases above the threshold frequency were considered for the candidate phrase pool. Thus, phrases that have zero frequency in Table 12 could in fact have a very low, but finite, frequency. Second, the phrases for the co-occurrence computations were restricted to the Abstracts only. Thus, phrases that occurred in the Keywords or Title were not included.

Other topical areas with patterns of USA predominance include oceanography and weather (SEA, OCEAN, FRONTS, PACIFIC, ICE, EL NINO, MESOSCALE, SEDIMENT, BAROTROPIC, DEEP WATER, SHALLOW-WATER, WATER DEPTH), aerodynamics (NAVIER-STOKES, VORTICITY, BOUNDARY LAYER, AERODYNAMIC, AIRCRAFT, AEROELASTIC, WIND-TUNNEL, ANGLE OF ATTACK), semiconductors (SEMICONDUCTOR, SEMICONDUCTOR LASER (S)), and encryption (ENCODING, DECODING). In fact, perusal of the lower frequency raw data terms relating to coding shows almost no phrases in any of the variants in the China literature. Again, many of the oceanography/ weather-related papers reflect large-scale experimental programs, from which more data would be available to a developed nation than a developing nation.

Because of the two caveats on the numbers in Table 12 presented previously, the phrases discussed above that reflected areas of USA dominance relative to China were inserted into the SCI, to validate the results. All the fields were examined, with no threshold on phrase frequency. The USA still predominated heavily, by a factor of about five relative to the normalized China frequencies. Thus, the simple method presented here provides the correct order of magnitude answer, but the actual ratio values are overly optimistic. In fact, this combination of using the simple method to identify major technical emphasis differences between countries, followed by a more targeted and detailed analysis of the SCI, is probably a reasonable prototype for a production-level analysis.

While these examples and the associated analysis are very abbreviated due to space limitations, the capability offered is intrinsically very powerful. The high frequency phrase/ low frequency phrase relational technique allows a microcasm of the total text mining study to be performed for any high frequency phrase, or combination of high frequency phrases. When relational indicators are used (not shown in this example), tens, or even hundreds, of low frequency phrases can be identified as relating to a high frequency phrase (depending on the total number of phrases used, and the threshold values of the numerical relational indicators chosen). These low frequency phrases can be categorized into a taxonomy, allowing the technical and bibliometric infrastructure for the high frequency phrase/ concept to be obtained.

ES-5. Observations on Results

This section addresses balance or imbalance of Nonlinear Dynamics with respect to different parameters.

A) Type of Research

In contrast to many of the previous topical text mining studies performed, Nonlinear Dynamics appears to be balanced among theory, experiment, and computational modeling. There is substantial phrase representation in all these research segments.

B) Categories of Research

Compared to most text mining studies performed previously by the first author, Nonlinear Dynamics seems heavily weighted toward basic research. No applied research journals were evident. No companies appeared in the institutional production category, and the only industry appearance was reflected by one of the most cited authors.

However, given the large volume of research activity, the discipline appears poised to transition into applications. There is already ongoing work on antennas, detectors, thermal combustors, and high power lasers that should find its way eventually to industry. The six volumes of experimental papers (not contained in the SCI) from the Proceedings of the Experimental Chaos conference (18-23) provide some indication of the breadth of potential applications.

C) Applications vs Tech Base

There appears to be a reasonable balance between generic tech base studies and more focused areas. Based on the journals and author institutions as stated above, as well as the types of phrases obtained, the focused area studies are more at the basic research level than applied.

Overall, there is a reasonable balance between chaos-oriented phenomena and nonlinear phenomena with no specified links to chaotic motion. Further, there appears to be a reasonable balance among techniques for analyzing chaotic systems, techniques for synchronizing and controlling coupled systems, and use of analytical tools for the nonlinear analysis of specific applications. Progress on methods to simplify solutions of high dimensional nonlinear equations, or on spatio-temporal (infinite dimensional) systems, has been slower.

Within the tech base areas, the priorities seem reasonable. Major emphasis is given to stability and cycling, reasonable emphasis is given to motion, scaling, modeling and simulation, and moderate emphasis is given to communication, control, coupling, thermodynamics, structures, and experiment. Hard divisions among many of these categories are somewhat blurred, because of overlap and potential multiple category assignment of phrases.

Within the focused areas, there is a reasonable balance among physical, environmental, engineering, and life sciences. However, there is a substantial imbalance between the 'hard' and 'soft' sciences. Essentially nothing in the phrase pattern analysis reflected input from the true social and political sciences. The number of articles retrieved from the Social Science Citation Index was four percent of the total articles retrieved. A reading of these 'social science' articles showed that: 1) 'chaos' is used in the vernacular in a not-insignificant fraction; 2) neuroscience and psychiatry/

psychology have reasonable representation, but they were captured in the phrase pattern analysis; 3) there is some effort on financial markets, but too widespread to generate high or mid-frequency phrase outputs; 4) there is minimal effort in the true social and political sciences.

One objective of the present study was to understand the applicability of Nonlinear Dynamics to political trends and predictions. Because chaos applies to deterministic equations, its applications to social systems are problemmatical, since social systems are too noisy to define deterministic trajectories. Too much information is missing in social/ economic systems to model the system accurately enough to find chaos, although other nonlinear responses are apparent. For example, the stock market has dramatic changes, and WWI started over a single assassination.

The documented applications in these social science areas are minimal. There may be a variety of causes in addition to noisy data mentioned above. In the present high tech world economy, both commercial and military, research sponsoring organizations may be far more interested in pursuing 'hard' science applications of Nonlinear Dynamics than 'soft' science applications.

Thus, money for social and political science research in Nonlinear Dynamics may not be available. In addition, because of potential sensitivities of political and social structure dynamics and trends, Nonlinear Dynamics studies may in fact be ongoing, but not published in the open literature. Given the inherent strong feedback and non-linearities in social group situations and organizations at all levels, one would expect that Nonlinear Dynamics could provide useful insights for analyzing and predicting social and political trends.

At a minimum, some of the concepts of Nonlinear Dynamics may be useful to 'softer' science applications, including bifurcations of behaviors, extreme sensitivity to initial conditions, pattern formation, attractors, repellers, and orbits. For example, there is an effort at ONR in war gaming based on cellular automata that has aspects of pattern formation (complexity) arising from simple rules. Flanking maneuvers appear, but have not been explicitly programmed. For all practical purposes, applicability of Nonlinear Dynamics to the 'softer' sciences remains unexplored.

D) Regional

Most previous text mining studies have shown the USA to be dominant in research output, and the Nonlinear Dynamics study is no exception. However, the difference between the USA and the other producers appears to be greater. This imbalance has been reduced over the past decade, from a factor of four greater than its nearest competitor to a factor of three, but it is still substantial. China has ascended as a major competitor, but does not appear to be involved in major areas in which the USA is not working. There is a reasonable balance between Europe and Asia, but still a substantial under-representation from the developing nations.

ES-6. Final Observations

The different statistical and non-statistical taxonomies generated above used different methodologies and some different phrases. Therefore, the results are not directly comparable. A taxonomy that reflects the levels of effort and specific research thrusts would have the structure of the non-statistical Abstract field taxonomy. A taxonomy that reflects commonality of categories would have the structure of the statistical taxonomies.

This paper has presented a number of advantages of using DT and bibliometrics for deriving technical intelligence from the published literature. Large amounts of data can be accessed and analyzed, well beyond what a finite group of expert panels could analyze in a reasonable time period. Preconceived biases tend to be minimized in generating roadmaps. Compared to standard co-word analysis, DT uses full text, not index words, and can make maximum use of the rich semantic relationships among the words. It also has the potential of identifying low occurrence frequency but highly theme related phrases that are 'needles-in-a-haystack', a capability unavailable to any of the other co-occurrence methods.

Combined with bibliometric analyses, DT identifies not only the technical themes and their relationships, but relationships among technical themes and authors, journals, institutions, and countries. Unlike other roadmap development processes, DT generates the roadmap in a 'bottom-up' approach. Unlike other taxonomy development processes, DT can generate many different types of taxonomies (because it uses full text, not key words) in a 'bottom-up' process, not the typical arbitrary 'top-down' taxonomy specification process. Compared to co-citation analysis, DT can use any type of text, not only published literature, and it is a more direct approach to identifying themes and their relationships.

The maximum potential of the DT and bibliometrics combination can be achieved when these two approaches are combined with expert analysis of selected portions of the database. If a manager, for example, wants to identify high quality research thrusts as well as science and technology gaps in specific technical areas, then an initial DT and bibliometrics analysis will provide a contextual view of work in the larger technical area; i.e., a strategic roadmap. With this strategic map in hand, the manager can then commission detailed analysis of selected abstracts to assess the quality of work done as well as identify work that needs to be done (promising opportunities).

1. INTRODUCTION

Science and technology are assuming an increasingly important role in the conduct and structure of domestic and foreign business and government. In the highly competitive civilian and military worlds, there has been a commensurate increase in the need for scientific and technical intelligence to insure that one's perceived adversaries do not gain an overwhelming advantage in the use of science and technology. While there is no substitute for direct human intelligence gathering, there have become available many techniques that can support and complement it. In particular, techniques that identify, select, gather, cull, and interpret large amounts of technological information semi-automatically can expand greatly the capabilities of human beings in performing technical intelligence.

One such technique is DT (2, 3, 4), a system for analyzing large amounts of textual computerized material. It includes algorithms for extracting multi-word phrase frequencies and phrase proximities from the textual databases, coupled with the topical expert human analyst to interpret the results and convert large volumes of disorganized data to ordered information. Phrase frequency analysis (occurrence frequency of multi-word technical phrases) provides the pervasive technical themes of a database, and the phrase proximity (physical closeness of the multi-word technical phrases) analysis provides the relationships among pervasive technical themes, as well as among technical themes and authors/journals/institutions/countries, etc. The present paper describes use of the DT process, supplemented by literature bibliometric analyses, to derive technical intelligence from the published literature of Nonlinear Dynamics science and technology.

Nonlinear Dynamics, as defined by the authors for this study, is that class of motions in deterministic physical and mathematical systems whose time evolution has a sensitive dependence on initial conditions. Since one of the key outputs of the present study is a query that can be used by the community to access relevant Nonlinear Dynamics documents, a recommended query based on this study is presented in total. This query serves as the operational definition of Nonlinear Dynamics, and its development is discussed in detail in the database generation section.

To execute the study reported in this paper, a database of relevant Nonlinear Dynamics articles is generated using the iterative search approach of Simulated Nucleation (5, 6). Then, the database is analyzed to produce the following characteristics and key features of the Nonlinear Dynamics field: recent prolific Nonlinear Dynamics authors; journals that contain numerous Nonlinear Dynamics papers; institutions that produce numerous Nonlinear Dynamics papers; keywords most frequently specified by the Nonlinear Dynamics authors; authors, papers and journals cited most frequently; pervasive technical themes of Nonlinear Dynamics; and relationships among the pervasive themes and sub-themes.

What is the importance of applying DT and bibliometrics to a topical field such as Nonlinear Dynamics? The roadmap, or guide, of this field produced by DT and bibliometrics provides the demographics and a macroscopic view of the total field in the global context of allied fields. This allows specific starting points to be chosen rationally for more detailed investigations into a specific topic of interest. DT and bibliometrics do not obviate the need for detailed investigation of the literature or interactions with the main performers of a given topical area in order to make a substantial contribution to the understanding or the advancement of this topical area, but allow these detailed efforts to be executed more efficiently. DT and bibliometrics are quantity-based measures (number of papers published, frequency of technical phrases, etc.), and correlations with intrinsic quality are less direct. The direct quality components of detailed literature investigation and interaction with performers, combined with the DT and bibliometrics analysis, can result in a product highly relevant to the user community.

2. BACKGROUND

2.1 Overview

The information sciences background for the approach used in this paper is presented in (7). This reference shows the unique features of the computer and co-word-based DT process relative to other roadmap techniques. It describes the two main roadmap categories (expert-based and computer-based), summarizes the different approaches to computer-based roadmaps (citation and co-occurrence techniques), presents the key features of classical co-word analysis, and shows the evolution of DT from its co-word roots to its present form.

The DT method in its entirety requires generically three distinct steps. The first step is identification of the main themes of the text being analyzed. The second step is determination of the quantitative and qualitative relationships among the main themes and their secondary themes. The final step is tracking the evolution of these themes and their relationships through time. The first two steps are summarized in 2.1.1 and 2.1.2. . Time evolution of themes has not yet been studied.

At this point, a variety of different analyses can be performed. For databases of non-journal technical articles (2), the final results have been identification of the pervasive technical themes of the database, the relationship among these themes, and the relationship of supporting sub-thrust areas (both high and low frequency) to the high-frequency themes. For the more recent studies in which the databases are journal article abstracts and associated bibliometric information (authors, journals, addresses, etc), the final results have also included relationships among the technical themes and authors, journals, institutions, etc (7-11).

2.1.1. First Step

The frequencies of appearance in the total text of all single word phrases (e.g., Matrix), adjacent double word phrases (e.g., Metal Matrix), and adjacent triple word phrases (e.g., Metal Matrix Composites) are computed. The highest frequency significant technical content phrases are selected by topical experts as the pervasive themes of the full database.

2.1.2. Second Step

2.1.2.1. Numerical Boundaries

For each theme phrase, the frequencies of phrases within +/-M (nominally 50) words of the theme phrase are computed for every occurrence of the theme phrase in the full text, and a phrase frequency dictionary is constructed. This dictionary contains the phrases closely related to the theme phrase. Numerical indices are employed to quantify the strength of this relationship. Both quantitative and qualitative analyses are performed by the topical expert for each dictionary (hereafter called cluster) yielding,

among many results, those sub-themes closely related to and supportive of the main cluster theme.

Threshold values are assigned to the numerical indices, and these indices are used to filter out the phrases most closely related to the cluster theme. However, because numbers are limited in their ability to portray the conceptual relationships among themes and sub-themes, the qualitative analyses of the extracted data by the topical experts have been at least as important as the quantitative analyses. The richness and detail of the extracted data in the full text analysis allow an understanding of the theme interrelationships not heretofore possible with previous text abstraction techniques (using index words, key words, etc.).

2.1.2.2. Semantic Boundaries

The approach is conceptually similar to 2.1.2.1, with the difference being that semantic boundaries are used to define the co-occurrence domain rather than numerical boundaries. The only semantic boundaries used for the present studies were paper Abstract boundaries. Software is being developed that will allow paragraphs or sentences to be used as semantic boundaries.

It is an open question as to whether semantic boundaries or numerical boundaries provide more accurate results. The elemental messages of text are contained in concepts or thoughts. Sentences or paragraphs are the vehicles by which the concepts or thoughts are expressed. The goal of text mining is to usually quantify relationships occurring in the concepts or thoughts, not in the fragments of their vehicles of expression. In particular, while intra-sentence relationships will be very strong, they may be overly restrictive for text mining purposes, and many cross-discipline relationships can be lost by adhering to intra-sentence relationships only. Intra-paragraph relationships are more inclusive and reasonable. For journal paper Abstracts of the type found in SCI, many Abstracts constitute a single paragraph.

2.2 Unique Study Features

The study reported in the present paper is in the latter (journal article abstract) category. It differs from the previous published papers in this category (7-11) in five respects. First, the topical domain (Nonlinear Dynamics) is completely different. Second, a much more rigorous statistically-based technical theme clustering approach is used. Third, bibliometric clustering is presented for two database fields: authors and countries. Fourth, a combination of fuzzy logic and manual aggregation was used in phrase selection to consolidate similar phrases, thereby allowing additional phrases to be used in the clusters and increase the scope of the clusters. Finally, the marginal utility algorithm was applied for the first time, allowing only the highest payoff terms to be included in the final query, and resulting in an efficient query.

3. DATABASE GENERATION

The key step in the Nonlinear Dynamics literature analysis is the generation of the database to be used for processing. There are three key elements to database generation: the overall objectives, the approach selected, and the database used. Each of these elements is described.

3.1 Overall Study Objectives

The main objective was to identify global S&T that had both direct and indirect relations to Nonlinear Dynamics. A sub-objective was to estimate the overall level of global effort in Nonlinear Dynamics S&T, as reflected by the emphases in the published literature.

3.2 Databases and Approach

For the present study, the SCI database was used. The approach used for query development was the DT-based iterative relevance feedback concept (5).

3.2.1 Science Citation Index/ Social Science Citation Index (12)

The retrieved database used for analysis consists of selected journal records (including the fields of authors, titles, journals, author addresses, author keywords, abstract narratives, and references cited for each paper) obtained by searching the Web version of the SCI for Nonlinear Dynamics articles. At the time the final data was extracted for the present paper (early 2002), the version of the SCI used accessed about 5600 journals (mainly in physical, engineering, and life sciences basic research) from the Science Citation Index, and over 1700 journals from the Social Science Citation Index. There is some overlap among the journals. For example, for 2001, there were 999620 total articles in the Science Citation Index, 149672 articles in the Social Sciences Citation Index, and 1104275 articles in the combined databases. Thus, 45017 articles were shared by both databases, four percent of the total, but thirty percent of the Social Science Citation Index.

The SCI database selected represents a fraction of the available Nonlinear Dynamics (mainly research) literature, that in turn represents a fraction of the Nonlinear Dynamics S&T actually performed globally (13). It does not include the large body of classified literature, or company proprietary technology literature. It does not include technical reports or books or patents on Nonlinear Dynamics. It covers a finite slice of time (1991, 2001). The database used represents the bulk of the peer-reviewed high quality Nonlinear Dynamics research literature, and is a representative sample of all Nonlinear Dynamics research in recent times.

To extract the relevant articles from the SCI, the Title, Keyword, and Abstract fields were searched using Keywords relevant to Nonlinear Dynamics. The resultant Abstracts were culled to those relevant to Nonlinear Dynamics. The search was

performed with the aid of two powerful DT tools (multi-word phrase frequency analysis and phrase proximity analysis) using the process of Simulated Nucleation (5).

An initial guery of Nonlinear Dynamics-related terms produced two groups of papers: one group was judged by domain experts to be relevant to the subject matter, the other was judged to be non-relevant. Gradations of relevancy or non-relevancy were not considered. An initial database of Titles, Keywords, and Abstracts was created for each of the two groups of papers. Phrase frequency and proximity analyses were performed on this textual database for each group. The high frequency single, double, and triple word phrases characteristic of the relevant group, and their boolean combinations, were then added to the query to expand the papers retrieved. Clustering of phrases into thematic categories was performed to help guide the selection of phrases (See Appendix 1 for a description of some of the clustering approaches). Phrases from each of the thematic categories were selected to insure balanced representation from the complete sample of relevant records. Similar phrases characteristic of the non-relevant group were effectively subtracted from the guery to contract the papers retrieved. The process was repeated on the new database of Titles, Keywords, and Abstracts obtained from the search. A few more iterations were performed until the number of records retrieved stabilized (convergence). The final phrase-based query used for the Nonlinear Dynamics study was shown in the Introduction.

In order to generate an efficient final query, a new process termed Marginal Utility was applied. At the start of the final iteration, a modified query (Q1-See Appendix 2) was inserted into the SCI, and records were retrieved. A sample of these records was then categorized into relevant and non-relevant. Each term in Q1 was inserted into the Marginal Utility algorithm, and the marginal number of relevant and non-relevant records in the sample that the query term would retrieve was computed (see Appendix 2 for these numerical indicators). Only those terms that retrieved a high ratio of relevant to non-relevant records were retained. Since (by design) each query term had been used to retrieve records from the SCI as part of Q1, the marginal ratio of relevant to non-relevant records from the sample would represent the marginal ratio of relevant to non-relevant records from the SCI. The final efficient query Q2, consisting of the highest marginal utility terms, was shown in the Introduction.

In the Marginal Utility algorithm, terms that co-occur strongly in records with previously-selected terms are essentially duplicative from the retrieval perspective, and can be eliminated. Thus, the order in which terms are selected becomes important. In the manual selection process described here, the candidate query terms were ordered by occurrence frequency, and tested for Marginal Utility. This may not be the most efficient use of Marginal Utility.

An automated query term selection algorithm using Marginal Utility is being developed presently. In the automated approach, all the terms in Q1 would be inserted into the Marginal Utility algorithm. The highest relevant frequency term (T1) would be selected first. Then, the Marginal Utility of every other term would be examined, in conjunction with only the first term selected. The term that retrieved the most marginal relevant

records (T2), above a pre-specified floor of relevant to non-relevant record ratio, would be added to the query. At this point, the query would consist of terms T1 and T2. Then, the Marginal Utility of every other term would be examined, in conjunction with only the first two terms selected. The same process that was used to select T2 would be used to select T3. This recursive process would be continued until either a pre-specified limit on total number of query terms, or the floor ratio of relevant records to non-relevant records retrieved, was reached.

The authors believe that queries of these magnitudes and complexities are required when necessary to provide a tailored database of relevant records that encompasses the broader aspects of target disciplines. In particular, if it is desired to enhance the transfer of ideas across disparate disciplines, and thereby stimulate the potential for innovation and discovery from complementary literatures (1), then even more complex queries using Simulated Nucleation may be required.

However, even with queries of this magnitude, not all records will be retrieved. As a point of reference, there were 204 articles with Abstracts published in the International Journal of Bifurcation and Chaos in 2001, of which 164 (~80%) were retrieved for this study. This was the highest fraction retrieved for any journal examined. For all the journals examined, some records have insufficient verbiage in their text fields, or have very non-standard verbiage relative to the main topical themes, such that they will not match with the query. These records are not retrieved. To retrieve records with non-standard very low frequency terminology from all the journals accessed would require queries that contain thousands of terms. The reader should think about how many fewer Nonlinear Dynamics records would have been accessed with the typical search queries containing about a half dozen terms, and how author and journal citation rates are negatively impacted by the combination of insufficient queries and insufficient verbiage in the record text fields.

4. RESULTS

The results from the publications bibliometric analyses are presented in section 4.1, followed by the results from the citations bibliometrics analysis in section 4.2. Results from the DT analyses are shown in section 4.3. The SCI bibliometric fields incorporated into the database included, for each paper, the author, journal, institution, and Keywords. In addition, the SCI included references for each paper.

The bibliometrics sections (4.1, 4.2) have three components. Some numerical indicators are presented for each bibliometric examined. Clustering results, that portray cohesive groups, are presented for most prolific authors only. Finally, the highest frequency bibliometrics (e.g., most prolific author, most prolific country) are presented for each bibliometric, and discussed.

The DT sections contain three components. First, the high frequency Keywords are grouped into 'natural' categories, and the picture they provide of the Nonlinear Dynamics literature (research, open literature, unclassified, non-proprietary) is

described. Second, the high frequency phrases from the Abstracts are grouped into 'natural' categories, and the picture they provide of the Nonlinear Dynamics literature is presented. Third, the high numerical indicator phrases from the proximity analyses of the Abstracts and other portions of the database (author names, article titles, journal names, author addresses) are grouped into 'natural' categories, and the picture they provide of the Nonlinear Dynamics literature is shown. The meaning of the term 'natural' is that these categories were not prescribed beforehand. From observation of the hundreds of different phrases and their frequencies, categories useful for interpreting and describing the main literature findings appeared to emerge.

The analytical approaches taken for the first three components (Keyword phrase frequency, Abstract phrase frequency, Abstract phrase proximity) are based on their fundamental data structures. The Keyword and Abstract phrase frequencies are essentially quantity measures. They lend themselves to 'binning', and addressing adequacies and deficiencies in levels of effort. They do not contain relational information, and therefore offer little insight into S&T linkages.

The phrase proximity results are essentially relational measures, although some of the proximity results imply levels of effort that support specific S&T areas. The phrase proximity results mainly offer insight into S&T linkages, and have the potential to help identify innovative concepts from disparate disciplines (1). Thus, the Keyword and Abstract phrase frequency analyses will be addressed to adequacy of effort, and the phrase proximity analyses will be addressed to relationships primarily and supporting levels of effort secondarily.

4.1 Publication Statistics on Authors, Journals, Organizations, Countries

The first group of metrics presented is counts of papers published by different entities. These metrics can be viewed as output and productivity measures. They are not direct measures of research quality, although there is some threshold quality level inferred, since these papers are published in the (typically) high caliber journals accessed by the SCI.

4.1.1 Prolific Nonlinear Dynamics Authors

Previous DT/ bibliometrics studies were conducted of the technical fields of: 1) Near-earth space (NES) (8); 2) Hypersonic and supersonic flow over aerodynamic bodies (HSF) (7); 3) Chemistry (JACS) (9) as represented by the Journal of the American Chemical Society; 4) Fullerenes (FUL) (10); 5) Aircraft (AIR) (11); 6) Hydrodynamic flow over surfaces (HYD); 7) Electric power sources (EPS); and 8) the non-technical field of research impact assessment (RIA). Overall parameters of these studies from the SCI database results and the current Nonlinear Dynamics study are shown in Table 1. In addition, in the present study, only four percent of the total retrieved papers derived from the Social Sciences Citation Index. The remaining 96 percent derived from the Science Citation Index.

TABLE 1 - DT STUDIES OF TOPICAL FIELDS

TOPICAL AREA	NUMBER OF SCI	YEARS
	ARTICLES	COVERED
1) NEAR-EARTH SPACE (NES)	5480	1993-MID 1996
2) HYPERSONICS (HSF)	1284	1993-MID 1996
3)CHEMISTRY (JACS)	2150	1994
4) FULLERENES (FUL)	10515	1991-MID 1998
5) AIRCRAFT (AIR)	4346	1991-MID 1998
6) HYDRODYNAMICS (HYD)	4608	1991-MID 1998
7) ELECTRIC POWER SOURCES (EPS)	20835	1991-BEG 2000
8) RESEARCH ASSESSMENT (RIA)	2300	1991-BEG 1995
9) NONLINEAR DYNAMICS (NONLIN)	6118	2001

These studies yielded: 1) 3.37 authors per paper for the NES results; 2) 2.63 authors per paper for the HSF results; 3) 3.79 authors per paper for the JACS results; 4) 3.92 authors per paper for the FUL results; 5) 2.09 authors per paper for the AIR results; 6) 2.29 authors per paper for the HYD results; and 7) 2.90 authors per paper for the EPS results. A previous study on the non-technical field of research impact assessment (RIA) (9) yielded about 1.68 authors per paper.

In the present Nonlinear Dynamics study, two types of computational linguistics analysis were performed on the author data field in the database. First, a frequency count of author appearances was made from the author field in the database, to identify the most prolific authors. Second, a clustering analysis was performed on the list of author appearances, to identify tightly-knit multi-author groups. The clustering methodology (also used in the analysis of the Abstract free text field to generate technology taxonomies) is described in Appendix 1.

4.1.1.1 Author Frequency Results

There were 6118 papers retrieved, 12136 different authors, and 16370 author listings. The occurrence of each author's name on a paper is defined as an author listing. While the average number of listings per author is about 1.34, the nineteen most prolific authors (see Table 2A) have listings more than an order of magnitude greater than the average. The number of papers listed for each author are those in the database of records extracted from the SCI using the query, not the total number of author papers listed in the source SCI database.

Of the nineteen most prolific authors listed in Table 2A, six are from China. In fact, eight are from the Far East, four are from Western Europe, one is from Eastern Europe, five are from North America, and one is from South America. Seventeen are from universities, and two are from research institutes.

To determine the trends in this regional mix of prolific authors, the same query was applied to 1991 only. Table 2B lists the most prolific authors for 1991.

The regional mix of authors has some major differences from the 2001 results. Of the nineteen most prolific authors listed in Table 2B, <u>none</u> are from the Far East, eight are from the USA, nine are from Western Europe, and two are from Eastern Europe. Eighteen are from universities, and one is from a research institute.

Only two names were common to both lists, Ott and Grebogi. However, some researchers can have an off year for a number of reasons, so individual comparisons over two years, especially two widely separated years, may not be overly important. More important are country comparisons, and maybe institutional comparisons to some extent. These entities integrate over many individuals, and their performance would be more reflective of national policy. In this regard, the aggregate shift of prolific performers from the NATO countries in 1991 to those of the Far East in 2001 stands out.

4.1.1.2 Clustering Results

Appendix 1 presents three clustering approaches for generating groups of related technical areas. The base data is a square co-occurrence matrix of the highest frequency technical phrases. The two statistical clustering processes listed can also be extrapolated to clustering authors, and other bibliometric quantities. A square co-occurrence matrix of the 253 most prolific authors (each matrix element represents the number of times each author pair is listed on the same paper) was generated, and clusters of related authors were then generated by the two statistical methods: factor matrix and multi-link aggregation.

4.1.1.2.1 Factor Matrix

The co-occurrence matrix was converted to a correlation matrix using the TechOasis software package. Then, the correlation matrix was converted to a factor matrix using the WINSTAT software package. Each matrix element contains the factor loading, a measure of the importance of each author to each factor. The number of factors was unconstrained, but the eigenvalues had a floor of unity. Practically, this means that each factor provides some additional useful information.

Appendix 3A contains the complete factor matrix for all 253 authors. Factor loading values above a threshold were shaded. Each column represents one factor, and the dark vertical bands in each column represent the essential contributors to each factor. The most cohesive factors start from the left column, and proceed to decrease in strength monotonically to the right. Thus, the strongest factor is the first, consisting of the authors ranging from Khan to Ghosh. Additionally, since the factors are not fully orthogonal, some authors can be connected strongly to more than one factor. Therefore, all the authors that represent the core of a factor are not necessarily presented in contiguous form. For example, the initial display of strong contributors to factor 4 is shown near the top: Liu, Davis, and Aida. Further down the column, it is seen that Liu and Chen are strong contributors as well, but they forge an even stronger

link when allied with Tang. Based on name ethnicity alone, intra-country clustering appears to be the dominant form of grouping. This will be examined later with country clustering.

4.1.1.2.2 Multi-Link Aggregation

To obtain a slightly different perspective on groupings, as well as to obtain more detail into sub-groupings within each factor, multi-link aggregation was performed. The co-occurrence matrix was normalized, and clusters of related authors were generated using the multi-link aggregation method of the WINSTAT software package described in Appendix 1.

Appendix 3B contains the full dendogram for the 253 most prolific authors. The ordinate is the 'distance', a measure of the coupling strength between authors, or groups of authors. Smaller 'distance' means stronger coupling. The abcissa is authors, and positioning of an author, or group of authors, along the axis also reflects the relationships among authors or groups.

The authors from Factor 1 of the factor matrix are shown to constitute a cluster (at the bottom of the dendogram). Additionally, the detailed structure within the Factor 1 cluster is evident from the dendogram. Khan and Gupta form a very tightly knit unit; that unit in combination with Sarkar forms a tightly knit unit and, in combination with Ghosh, forms a moderately knit unit.

Table 2C is a co-occurrence matrix of the authors contained in Factor 1.

TABLE 2C - FACTOR 1 AUTHORS CO-OCCURRENCE MATRIX

	KHAN M	GUPTA MR	SARKAR S	GHOSH S
KHAN M	5	5	5	5
GUPTA MR	5	5	5	5
SARKAR S	5	5	6	5
GHOSH S	5	5	5	7

The closeness of the sub-group members depicted schematically on the dendogram is confirmed by the actual numbers of papers. All of Khan's and Gupta's five papers are published with each other and with Sarkar and Ghosh as well. Five out of six of Sarkhar's papers are published with the other three authors, as are five out of seven of Ghosh's papers.

4.1.2 Journals Containing Most Nonlinear Dynamics Papers

There were 1151 different journals represented, with an average of 11.90 papers per journal. The journals containing the most nonlinear dynamics papers (see Table 3A) had more than an order of magnitude more papers than the average.

TABLE 3A - JOURNALS CONTAINING MOST PAPERS - 2001

ASTROPHYS. J.	45

The majority of the journals are physics, with the remainder divided between mathematics and electronics. Phys Rev E is the Physical Review journal assigned to chaos, while Phys Rev letters receives important papers for rapid publishing. Many (not all) of the other journals do not focus on nonlinear topics, but include papers in their specialties that also involve nonlinear aspects.

To determine the trends in journals containing the most nonlinear dynamics papers, the results from 1991 are examined. Table 3B contains the top twenty journals.

While the most prolific authors could be expected to change over a decade, for a number of reasons, the most prolific journals should be more stable. Comparison of Tables 3A and 3B shows this to be true. Of the nineteen most prolific journals, eleven are in common. For 2001, two journals were added devoted solely to chaos and closely related topics (CHAOS SOLITONS FRACTALS, INTERNATIONAL JOURNAL OF BIFURCATION AND CHAOS). Perhaps the largest change is the drop of Physical Review A from first in 1991 to twelfth in 2001, and the appearance of Physical Review E as first in 2001. Phys Rev E was split from Phys Rev A during the past decade, and received the Physical Review assignment for papers in chaos.

4.1.3 Institutions Producing Most Nonlinear Dynamics Papers

A similar process was used to develop a frequency count of institutional address appearances. It should be noted that many different organizational components may be included under the single organizational heading (e.g., Harvard Univ could include the Chemistry Department, Biology Department, Physics Department, etc.). Identifying the higher level institutions is instrumental for these DT studies. Once they have been identified through bibliometric analysis, subsequent measures may be taken (if desired) to identify particular departments within an institution.

Of the thirty most prolific institutions, fourteen are from the USA, seven are from Western Europe, five are from Asia, two are from Eastern Europe, one is from Latin America, and one is from the Middle East. Twenty-five are universities, and the remaining institutions are research institutes. The most prolific institutions for nonlinear dynamics papers correlate well with institutions that have Centers for nonlinear dynamics.

To determine the trends in institutions containing the most nonlinear dynamics papers, the results from 1991 were examined. Table 4B contains the top thirty institutions.

Of the thirty most prolific institutions in 1991, twenty are from the USA, five are from Western Europe, three are from Eastern Europe, one is from Asia, and one is from Canada. The major shift is substitution of Asian institutions for USA institutions. In addition, twenty-five institutions are universities, and five are research institutes.

There are at least five factors that underlay the quality and quantity of nonlinear dynamics research. First, nonlinear dynamics is on the cutting edge of physics research, and has applicability to many different S&T disciplines. It is a prime research area for an institution's academic expansion.

Second, advances in nonlinear dynamics requires people who are intelligent and well-trained in physics and mathematics. Asian countries have large populations, and large numbers of researchers, well trained in physics, mathematics, and other fundamental disciplines. They tend to score well in international scientific education competitions. They have the educational foundations for becoming major contributors.

Third, much of nonlinear dynamics requires the extensive use of computers, to perform and display results of theoretical computations, and support analysis of experimental data. The growth of affordable personal computers, mainly in the decade of the 90s, has allowed poor third-world countries to acquire modern computational facilities, and compete as almost equals in this area.

Fourth, there is a strong theoretical component, that requires substantial intellect and minimal funding. This provides poorer countries with a large supply of well-educated professionals the opportunity to gain high visibility in theoretical studies of nonlinear dynamics.

Fifth, there is a strong data analysis component, with three aspects to the data analysis:

1) the ease in obtaining the data; 2) the ability to analyze the data; 3) the tools needed to support the analysis. Item 2) requires well-trained professionals, and the proliferation of such people in Asian countries was addressed previously. Item 3) involves modern computers, and the recent proliferation of these facilities in Asian countries was also addressed previously. Item 1) depends on the data source. For data that requires expensive laboratory or field or flight tests to acquire, the poorer countries are at a distinct dis-advantage relative to the developed countries. For example, in the China/ USA comparison presented later, it is shown that China has very little effort in disciplines such as space phenomena analysis or controlled fusion plasma analysis. This is undoubtedly related to the high costs of acquiring data in these areas, and China's lack of a substantial experimental effort in these areas. However, there is much data that can be analyzed with the techniques of nonlinear dynamics that does not require expensive facilities, and the less affluent Asian countries can focus substantial efforts in these areas.

4.1.4 Countries Producing Most Nonlinear Dynamics Papers

There are 78 different countries listed in the results for 2001. The country bibliometric results are summarized in Table 5A and shown graphically in Figure 1. The dominance of a handful of countries is clearly evident.

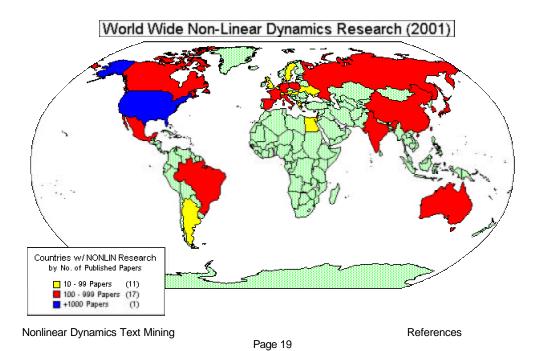

TABLE 5A - PROLIFIC COUNTRIES - 2001

COUNTRY	# PAPERS
USA	1797
PEOPLES R CHINA	588
GERMANY	585
JAPAN	470

SWEDEN	71
ARGENTINA	70
DENMARK	60
SCOTLAND	55
SWITZERLAND	53
AUSTRIA	47
HUNGARY	47
EGYPT	35

There appear to be two dominant groupings. The first group is the USA. It has as many papers as the members of the second group, People's Republic of China, Germany, and Japan.

FIGURE 1 – COUNTRIES WITH THE MOST NONLINEAR DYNAMICS PAPERS – 2001

To determine the trends in countries containing the most nonlinear dynamics papers, the results from 1991 were examined. Table 5B summarizes results from the top twenty countries, and Figure 2 displays these results graphically.

World Wide Non-Linear Dynamics Research (1991)

Nonlinear Dynamics Text Mining

References

The major shift is the increased ranking of People's Republic of China from 11th in 1991 to 2nd in 2001, and the concomitant increase in numbers of papers from 63 to 584. To place China's increase in Nonlinear Dynamics papers in perspective, it is compared to China's overall increase in SCI papers from 1991 to 2001. In 1991, China had 8174 entries in the SCI, and in 2001, China had 36765 entries in the SCI. Thus, while China's papers in Nonlinear Dynamics in the SCI increased by a factor of ~9.25 from 1991 to 2001, China's overall increase in SCI papers from 1991 to 2001 was a factor of ~4.5. Thus, China's Nonlinear Dynamics papers outpaced its average growth of SCI papers by a factor of ~ 2.

Appendix 4 contains a co-occurrence matrix of the top 15 countries. In terms of absolute numbers of co-authored papers, the USA major partners are Germany, China, France, Canada, and England. Interestingly, the USA is China's dominant major partner, having four times the number of co-authored papers with China (72) as China's next larger partner, Canada (18). Overall, countries in similar geographical regions tend to co-publish substantially, the US being a moderate exception.

4.2 Citation Statistics on Authors, Papers, and Journals

The second group of metrics presented is counts of citations to papers published by different entities. While citations are ordinarily used as impact or quality metrics (14), much caution needs to be exercised in their frequency count interpretation, since there are numerous reasons why authors cite or do not cite particular papers (15, 16).

The citations in all the retrieved SCI papers were aggregated, the authors, specific papers, years, journals, and countries cited most frequently were identified, and were presented in order of decreasing frequency. A small percentage of any of these categories received large numbers of citations. From the citation year results, the most recent papers tended to be the most highly cited. This reflected rapidly evolving fields of research.

4.2.1 Most Cited Authors

The most highly cited authors are listed in Table 6.

Of the twenty most cited authors, ten are from the USA, seven from Western Europe, one from Russia, one from Japan, and one from Latin America. This is a far different distribution from the most prolific authors of 2001, where eight of nineteen were from the Far East. This distribution of most cited authors more closely resembles the distribution of most prolific authors from 1991, where none were from the Far East.

There are a number of potential reasons for this difference between most prolific and cited authors in 2001. The most prolific may not be the highest quality, or many of the most prolific authors could be relatively recent, and insufficient time has elapsed for their citations to accumulate. In another three or four years, when the papers from present-day authors have accumulated sufficient citations, firmer conclusions about quality can be drawn.

The lists of nineteen most prolific authors from 2001 and twenty most highly cited authors only had five names in common (OTT, NAYFEH, GASPARD, GREBOGI, LAI). This phenomenon of minimal intersection has been observed in all other text mining studies performed by the first author.

Fifteen of the authors' institutions are universities, four are government-sponsored research laboratories, and one is a private company.

The citation data for authors and journals represents citations generated only by the specific records extracted from the SCI database for this study. It does not represent all the citations received by the references in those records; these references in the database records could have been cited additionally by papers in other technical disciplines.

4.2.2 Most Cited Papers

The most highly cited documents are listed in Table 7.

The theme of each paper is shown in italics on the line after the paper listing. The order of paper listings is by number of citations by other papers in the extracted database analyzed. The total number of citations from the SCI paper listing, a more accurate measure of total impact, is shown in the last column on the right.

Physical Review Letters contains the most papers by far, four out of the twenty listed. Most of the journals are fundamental science journals, and most of the topics have a fundamental science theme. The majority of the papers are from the 1990s, with seven from the 1980s, one from the 1970s, and one extremely highly cited paper being from 1963. This reflects a dynamic research field, with seminal works being performed in the recent past.

Eight of the papers address issues related to chaos, with the dominant themes being conditions for determining chaos, and properties of strange attractors. Four of the papers address issues related to synchronization, with the focus on coupled chaotic oscillators.. Three of the papers address issues related to control, emphasizing self-controlling feedback. One paper addresses stability-related issues, focusing on bifurcations, and one paper focuses on quantum chaos. There are three nonlinear dynamics books in the top twenty cited documents.

Thus, the major intellectual emphasis of cutting edge Nonlinear Dynamics research, as evidenced by the most cited papers, is well aligned with the intellectual heritage and performance emphasis, as will be evidenced by the clustering approaches.

4.2.3. Most Cited Journals

The most highly cited journals are listed in Table 8.

TABLE 8 – MOST CITED JOURNALS (cited by other papers in this database only)

Nonlinear Dynamics Text Mining

References

JOURNAL	TIMES CITED
PHYS REV LETT	10786
PHYS REV E	5310
PHYS REV A	3603
PHYSICA D	3579
PHYS LETT A	2308
J CHEM PHYS	2138
J FLUID MECH	2002
PHYS REV B	1969

SCIENCE	1256
PHYS REV D	1215
J PHYS A-MATH GEN	1073
PHYS FLUIDS	907
J ATMOS SCI	871
REV MOD PHYS	864
PHYS REP	813
J STAT PHYS	790
CHAOS	777

The first two groups of cited journals clearly stand out. PHYS REV LETT received almost as many cites as the three journals in the next group (PHYS REV E, PHYS REV A, PHYSICA D), or even the five journals in the following group (PHYS LETT A, J CHEM PHYS, J FLUID MECH, PHYS REV B, NATURE). PHYS REV LETT emphasizes rapid publication of 'hot' topics, and would therefore tend to establish primacy in an emerging field. Since one aspect of citations is identifying the original literature of a new topic, a credible journal with these characteristics would tend to receive large numbers of citations.

Unlike the relatively disjoint relationship between most prolific authors in 2001 and most cited authors, the relationship between most prolific journals in 2001 and most cited journals was much closer. Nine of the ten most highly cited journals were also on the list of twenty most prolific journals in 2001. The more applied journals on the most prolific list for 2001 are replaced by the more fundamental journals on the most cited list.

The authors end this bibliometrics section by recommending that the reader interested in researching the topical field of interest would be well-advised to, first, obtain the highly-cited papers listed and, second, peruse those sources that are highly cited and/or contain large numbers of recently published papers.

4.3 Database Tomography Results

Nonlinear Dynamics Text Mining

References

There are two major analytic methods used in this section to generate taxonomies of the SCI databases: non-statistical clustering, based on <u>phrase frequency analysis</u>, and statistical clustering, based on <u>phrase proximity analysis</u>. They are described in Appendix 1.

4.3.1. Taxonomies

4.3.1.1 Non-Statistical Clustering

4.3.1.1.1 Keyword Taxonomy

All the Keywords from the extracted SCI records, and their associated frequencies of occurrence (with a threshold frequency of nine), were tabulated, and then grouped into categories by visual inspection. The phrases were of two types: applications-related and phenomena or tech-base-related. While the application sub-categories were relatively independent, there was substantial overlap among some of the tech-base categories. The detailed taxonomy results are presented in Appendix 5. Within each sub-category, thrust areas are presented in approximate frequency appearance order. These results are displayed in Table 9, and summarized now.

There are eight distinct applications categories, with four levels of stratification based on phrase frequency summations. Fluid Flow is the dominant stratification level, with the main emphasis being turbulence, convective transport, and diffusion. The second stratification level consists of Optics and Brain. The Optics emphases are lasers and associated nonlinear phenomena, while the Brain emphases are neural networks and analyses of broader neural system signals. The third stratification level consists of Environment and Cosmology. The Environment emphases are earthquakes and storms, while the Cosmology emphases center around evolution of the universe. The fourth stratification level consists of Materials, Chemistry, and Plasma (mostly fusion physics based). The Materials emphasis are split between solid mechanics/ structures issues and electronic properties/ applications issues.

There are fourteen tech base categories, also with four main stratification levels based on phrase frequency summations. The dominant level is Motion, consisting of the subcategories Evolution and Chaos. Evolution emphases are attractors and nonlinear dynamics. The second level consists of Stability, comprised of the sub-categories Stability and Maps. Stability emphases are bifurcations and the transitions to instability, while Maps emphasizes Poincare's surface intersections. The third level comprises Cycling and Modeling and Simulation, with Cycling further categorized into Oscillations, Periodicity, and Waves. Under Oscillations, nonlinear, chaotic, and coupled oscillators are emphasized, as well as limit cycles; under Periodicity, the focus is periodic orbits; and under Waves, the emphasis is traveling and solitary waves.

The fourth stratification level consists of Communication, Scaling, Thermodynamics, and Coupling. Communication comprises Signals and Circuits; Scaling comprises Quantum, Dimensionality, Localization, and Scaling; Thermodynamics comprises Entropy, Noise, Statistics, Dissipation, Thermodynamics, and Conservation; and Coupling comprises Synchronization and Resonance. Under Signals, time series analysis and the associated intermittency are emphasized; under Quantum, small particle motions and interactions are emphasized; under Dimensionality, different measures of fractal dimensions of strange attractors are emphasized; under Entropy, patterns and pattern formation are emphasized; under Noise, brownian motion is emphasized; under Dissipation, hysteresis and friction are emphasized; and under Resonance, stochastic resonance is emphasized.

4.3.1.1.2 Abstract Taxonomy

A taxonomy of nonlinear dynamics applications and phenomena was developed through visual inspection of the TextDicer Abstract phrase frequencies. The developed taxonomy was subsequently used to approximate global levels of emphasis (GLE). This type of analysis would help identify adequately and inadequately supported system and subsystem tech base areas. It could also differentiate the developed and developing technology components of a particular system.

The manual Abstract taxonomy was developed using two different approaches. The first approach used the marginal utility algorithm described in the information retrieval section. A list of Abstract phrases was generated by TextDicer, and high technical content phrases were selected. For each phrase selected, the records in which the phrase appeared was tagged. For each phrase selected, only those records that were previously untagged ('new' records) were counted for phrase frequency summation purposes.

This type of phrase frequency accounting had three effects. First, since Abstracts were counted, and only counted once, any type of multiple counting was eliminated. Second, all Abstracts had the same weighting. Any skewing due to Abstract length differences was eliminated. Third, only one theme per Abstract was counted. Thus, if an Abstract described multiple phenomena, only one was counted. Also, if an application and phenomena were described, only one or the other would be represented by the phrase selected. While the first two effects were viewed as positive normalizing effects, the third effect was viewed as negative. Much information was lost from the third effect, because of the counting of one phrase only per Abstract. In addition, the order in which the phrases were selected affected the frequency sums. The generic phenomena tended to be represented in the higher frequency Keywords, whereas the applications tended to be represented in the lower frequency Keywords. Since the higher technical content longer keywords were of interest because of the detail provided, selection started from the lower frequency Keywords and progressed to the higher frequency keywords.

The second taxonomy development approach used absolute Abstract phrase frequencies from TextDicer. Since the present incarnation of TextDicer allows multiple counting of nested phrases (e.g., METAL and METAL MATRIX are both counted for frequency summation purposes, and therefore METAL is counted twice), corrections are required to eliminate multiple counting. Thus, in the second approach, categories were generated by visual inspection, and phrases were assigned manually. The frequencies were corrected to counter the effects of nesting, and then the frequencies were summed for each category.

Table 10 contains both the manual Abstract taxonomy generated using the marginal utility algorithm and the manual Abstract taxonomy generated without the marginal utility algorithm. Appendix 6A contains the Abstract phrases (marginal utility) and their allocation to categories, and Appendix 6B contains the Abstract phrases (non-marginal utility) and their allocation to categories.

Both approaches produce the same categories, although the balance among categories differs. Overall, the ratio (.3) of Applications phrase frequencies (1391) to Phenomena phrase frequencies (4616) for the marginal utility approach is substantially higher than the ratio (.16) of Applications phrase frequencies (5180) to Phenomena phrase frequencies (28728) for the non-marginal utility approach. The query terms were all phenomena-related, and one would expect the Abstract terms to be predominately phenomena-related. Any application terms that arise in the Abstracts are secondary, and are of substantially lower frequency than the phenomena-related terms. Since the marginal utility approach started at the low frequency part of the spectrum in order to extract the more detailed technical phrases, it encountered a greater fraction of applications terms than had it started at the high frequency end. Since the marginal utility approach tags each record once, tagging a record with a low frequency application term would eliminate any high frequency phenomena-related term being counted.

Relative to the Keyword taxonomy, the Abstract taxonomies have two additional categories: Biology and Medical. While biological and medical terms can be found in the list of Keywords, they occur with a frequency lower than that used for cutoff. The reasons for this are unclear. In the Abstract phrase taxonomies, Biological and Medical are not the lowest frequency applications, and if the Keywords correlated with the Abstract phrases, one would expect Biology and Medicine to appear as Keyword taxonomy categories. It could be that: 1) the biomedical community uses a greater fraction of nonlinear dynamics phenomenological terms as Keywords than other application communities; 2) there is less agreement on medical terminology relative to other communities, and a greater variety of low frequency terms are used; or 3), a broader variety of medical sub-areas are being investigated with nonlinear dynamics than some of the other applications areas.

In addition, some new categories were generated for the Abstract taxonomies by fissioning categories in the Keywords taxonomy. For example, Optics in the Keywords taxonomy was split into Optics and Lasers for the Abstracts taxonomies, due to the substantially greater amount of Abstract phrase detail, but it is fundamentally the same category.

Now, the emphasis areas of the Abstract phrase categories will be summarized. Because the single Abstract theme focus of the marginal utility approach is too constraining for purposes of category emphasis estimation, only the non-marginal utility approach will be analyzed.

Applications can be stratified into four main levels, based on summation of phrase frequencies as figure-of-merit. The dominant level consists of Fluid Flow (1025) and Optics (854), the latter including both Optical (506) and Laser (348). Fluid Flow emphasizes turbulence, vorticity, and convection; Optics emphasizes lasers and beams (generically electromagnetic beams, but usually laser or light beams).

The second level consists of Brain (606). Brain emphasizes neuron firings, EEG, epilepsy, and cortex.

The third level consists of Chemistry (359), Cosmology (353), Environment (404), and Material (481), the latter including both Materials (217) and Solid State (264). Chemistry emphasizes reaction and diffusion rates, combustion, catalysis, and Belousov-Zhabotinsky reaction; Cosmology emphasizes galaxies, black holes, and planets; Environment emphasizes atmosphere, weather (wind, climate, storms, rainfall), and ecology; Material emphasizes polymers, viscoelasticity, crystals, semiconductors, diodes, and tunneling.

The fourth major level consists of Medical (204), Geology (274), and Biology (246), Medical emphasizes cardiovascular problems (cardiovascular, blood pressure, fibrillation, heart rate, ventricular, pacemaker), and infectious disease (infection, virus).

Geology emphasizes seismic events (earthquake, ground motion, landslide, seismic, volcanic), and Biology emphasizes genetics, DNA, and circadian rhythms.

Phenomena can be stratified into three main levels, based on summation of phrase frequencies as figure-of-merit. The dominant level consists of Stability (3854) and Cycling (3465). The Stability category can be divided into a Stability sub-category (3199) and a Maps sub-category (655). The Cycling category can be divided into an Oscillations sub-category (2106), a Periodicity sub-category (919), and a Wave sub-category (440).

Within the Stability category, the Stability sub-category emphasizes. Hopf, pitchfork, period-doubling, global, saddle-node, homoclinic, local, transcritical, blowout, primary, and subcritical bifurcations, and bifurcation points/ diagrams/ curves/ structure/ control/set/ buckling/ mechanism, stability and instability [LINEAR AND NONLINEAR STABILITY ANALYSIS, STABLE AND UNSTABLE PERIODIC ORBITS, ASYMPTOTIC STABILITY, ONSET OF INSTABILITY, UNSTABLE FIXED POINT(S), STABLE LIMIT CYCLE(S), UNSTABLE PERIODIC SOLUTIONS, CONDITIONS OF STABILITY, LINEAR STABILITY THEORY], Lyapunov criteria, and critical and equilibrium points; the Maps sub-category emphasizes Poincare, logistic, Henon, return, standard, circle, invertable and non-invertable, Ikeda, unimodal, area-preserving, symplectic, and quadratic maps, center, invariant, stable and unstable, slow, compact, homoclinic, inertial, riemannian, Stiefel, and symplectic manifolds, and normal forms.

Within the Cycling category, the Oscillations sub-category emphasizes oscillators, vibrators, and limit cycles; the Periodicity sub-category emphasizes homoclinic, circular, chaotic, periodic, and quasi-periodic orbits, period doubling, and periodic points; the Wave sub-category emphasizes acoustic, gravity, nonlinear, solitary, spiral, standing, traveling, and water waves, wave equations, fronts, and packets, and wave forms and numbers.

The second level consists of Motion (2571), Scaling (2562), and Modeling and Simulation (1931). The Motion category can be divided into an Evolution sub-category (1218), a Chaos sub-category (554), and an Attractors sub-category (799). The Scaling category can be divided into a Quantum sub-category (1210), a Dimensionality sub-category (491), a Scaling sub-category (739), and a Localization sub-category (122).

Within the Motion category, the Evolution sub-category emphasizes dynamical systems, nonlinear dynamics, chaotic dynamics, time and nonlinear evolution, system and population dynamics; the Chaos sub-category emphasizes chaotic systems, motions, orbits, regimes, states, scattering, and trajectories, onset of chaos, transition to chaos, deterministic chaos, routes to chaos, and spatiotemporal chaos; the Attractors sub-category emphasizes chaotic, global, strange, coexisting, fixed point, periodic, great, hyperchaotic, multiple, random, stable, compact, and dynamical attractors, basins, attracting sets, attractor networks and dimensions.

Within the Scaling category, the Quantum sub-category emphasizes dynamics of small particles [ELECTRONS, IONS, ATOMS, MOLECULES, NUCLEI, PROTONS], lattices, quantum chaos/ dots/ dynamics/ interference/ mechanics/ states/ systems, the Schrodinger equations, and billiard models; the Dimensionality sub-category emphasizes correlation, fractal, embedding, Hausdorff, generalized, range, high and low, and finite dimensions, and degrees of freedom; the Scaling sub-category emphasizes fractals, time and length scales, and self-similarity; the Localization subcategory emphasizes dynamical, nonlinear, spatial, weak, Anderson, and electron localization, intrinsic localized modes, locally transversal linearization, localization length, localized states, and local linearization.

The Modeling and Simulation category emphasizes nonlinear, ordinary and partial differential, stochastic differential, delay differential, functional differential, difference, Navier-Stokes, reaction-diffusion, Fokker-Planck, constitutive, algebraic, Klein-Gordon, KDV, Burger, Euler, Boltzmann, Duffing, Lorenz, Mathieu, and Kuramoto-Sivashinsky equations, equations of motion, control, genetic, numerical, learning, backpropagation, decoding, and Grassberger-Procaccia algorithms, simulated annealing, numerical, computer, dynamical, model, nonlinear, direct, stochastic, monte carlo, and molecular dynamics simulations. and neural network, finite element, nonlinear dynamical, mathematical, numerical, linear and nonlinear, oscillator, chaotic, neuron, circuit, fuzzy, stochastic, mechanical, food chain, and general circulation models.

The third level consists of Communication (1530), Control (1361), Coupling (1375), Thermodynamics (1247), Structures (1100), and Experiment (1073). The Communication category can be divided into a Signals sub-category (1081), a Circuits sub-category (220), a Communications sub-category (136), and a Code sub-category (61). The Coupling category can be divided into a Synchronicity sub-category (591), a Coupling sub-category (319), and a Resonance sub-category (465). The Thermodynamics category can be divided into a Noise sub-category (416), a Statistics sub-category (154), an Entropy sub-category (256), a Dissipation sub-category (303), and a Thermodynamics sub-category (118). The Structures category can be divided into a Nonlinear sub-category (678) and a States sub-category (422).

Within the Communication category, the Signals sub-category emphasizes chaotic, output and input, driving, control, beat, coupled, digital, error, external, microwave, nonlinear, and reference signals, time series, harmonic, anharmonic, and sub-harmonic, information and signal processing, and intermittency; the Circuits sub-category emphasizes electronic, chaotic, equivalent, nonlinear, shunt, and Pikovsky circuits; Josephson Junctions, and switches; the Communications sub-category emphasizes secure, chaotic, digital, and spread spectrum communications, and communication systems, communication channel the Code sub-category emphasizes coding and decoding, encryption, and security.

The Control category emphasizes feedback, delayed feedback, optimal, adaptive, nonlinear, chaos, robust, motion, tracking, active, mode, sliding mode, bifurcation,

variable structure, and hybrid control, feedback, feed-forward, back-propagation, control system/ law/ strategy/ algorithm/ design/ theory.

Within the Coupling category, the Synchronicity sub-category emphasizes phase, chaos, generalized, global, asymptotic, lag, projective, and adaptive synchronization, phase, frequency, mode, and injection locking, discrete breathers, and synchronization error; the Coupling sub-category emphasizes coupled chaotic, coupled systems, coupling strength, strong coupling, weak coupling, and unidirectional coupling; and the Resonance sub-category emphasizes stochastic, internal, parametric, coherence, nonlinear, strong, size, primary, magnetic, cyclotron resonance, and resonance frequencies/ modes/ states.

Within the Thermodynamics category, the Noise sub-category emphasizes white, gaussian, external, additive, colored, measurement, random, dynamical, channel, correlated, stochastic, and thermal noise, and noise reduction/ intensity/ correlation/ amplitude/ sources, and Brownian Motion; the Statistics sub-category emphasizes Bose-Einstein, Bayesian, Ergodicity, Markov Chain, spectral, eigenvector, and Poisson statistics, and statistical properties/ mechanics/ ensembles/ distributions/ moments/ physics/ theory; the Dissipation sub-category emphasizes energy, tidal, numerical, artificial, and viscous dissipation, dissipative systems/ solitons/ structures/ dynamics/ models/ chaos/ maps, hysteresis; the Entropy sub-category emphasizes Kolmogorov, topological, approximate, information, Neumann, Shannon, linear, maximum, and Tsallis entropy, entropy production/ balance/ correlation/ fluctuations/ flux/ perturbations, spatial, wave, and spatiotemporal patterns, and pattern formation and recognition; the Thermodynamics sub-category emphasizes thermodynamic limits and equilibrium, adiabatic approximation, and nonadiabatic systems and dust.

Within the Structures category, the Nonlinear sub-category emphasizes nonlinear systems/ interactions/ effects/ equations/ response/ terms/ regime/ phenomena/ function/ processes/ elastic/ prediction/ optimization/ stochastic/ viscoelastic/ dependence/ state/ boundary/ crystal/ structure; the States sub-category emphasizes ground, coherent, equilibrium, bound, stationary, excited, transition, basic, system, quiescent, rest and turbulent states, and state variables/ estimation/ vectors.

The Experiment category emphasizes experimental results/ data/ observations/ measurements/ evidence/ conditions/ models/ verification/ techniques/ apparatus/ device/ dynamics, numerical, laboratory, computer, simulation, independent, and physical experiments, electric, magnetic, and electromagnetic fields, MEMS, microscopy, and spectroscopy,

The remaining categories are small, and will not be discussed further.

4.3.1.2. Statistical Clustering

Two statistically-based clustering methods were used to develop taxonomies, factor matrix clustering and multi-link clustering. Both offer different perspectives on taxonomy

Nonlinear Dynamics Text Mining

References

category structure from the non-statistical manual clustering approach described above. None of the three approaches are inherently superior.

Appendix 1 describes the statistically-based clustering methodologies in more detail. Appendix 1A overviews the generic statistically-based clustering approach, Appendix 1B describes the factor matrix clustering, and Appendix 1C describes the multi-link clustering.

4.3.1.2.1. Factor Matrix Clustering

The highest frequency high technical content phrases, with record frequencies not below seven, were identified (640 phrases). Very similar phrases were consolidated (e.g., singulars/ plurals, full spellings/ acronyms, strong synonyms), as shown by the process in Appendix 7. A correlation matrix of the 253 resultant consolidated phrases was generated, and a factor analysis was performed using the WINSTAT statistical package. The eigenvalue floor was set equal to unity, and a factor matrix consisting of 20 factors resulted. A description of each factor, and their aggregation into a taxonomy, follows. The capitalized phrases in parentheses represent typical high factor loading phrases for the factor described. The complete factor matrix is presented in Appendix 8.

Factor 1 (BIFURCATIONS, STABILITY, POINCARE MAPS, PERIODIC MOTIONS, PERIODIC SOLUTIONS, PHASE PLANE, LIMIT CYCLES, PHASE PORTRAITS, FIXED POINTS, PERIOD DOUBLING, EQUILIBRIUM POINTS, also including LYAPUNOV EXPONENTS, NORMAL FORMS, FLOQUET THEORY) – focuses on stability of periodic systems, emphasizing onset and prediction of instabilities. Examines routes to chaos through bifurcation and associated period doubling, using reduced and normal forms of the Poincare map, as well as phase plane trajectories to plot the motions.

Factor 2 (CLASSICAL SYSTEM, CLASSICAL LIMIT, QUANTUM SYSTEMS, QUANTUM DYNAMICS, TRACE FORMULA, QUANTUM MECHANICS, TIME EVOLUTION, CLASSICAL DYNAMICS, DYNAMICAL EVOLUTION, BROWNIAN MOTION, also including QUANTUM-CLASSICAL CORRESPONDENCE, DECOHERENCE, COHERENT STATES) – focuses on correspondence between quantum dynamical systems and classical systems, especially focusing on the classical limit behavior of quantum systems, as well as the trace formula's semiclassical representation for a quantum system's density of states in terms of the periodic orbits of the underlying classical dynamics.

Factor 3 (RANDOM MATRIX THEORY, ENERGY LEVELS, SPECTRAL STATISTICS, STATISTICAL PROPERTIES, EIGENFUNCTIONS, QUANTUM-CLASSICAL CORRESPONDENCE, ERGODICITY, WAVE FUNCTIONS, also including CHAOS, PERIODIC ORBITS, QUANTUM DOTS) – focuses on potential links between the statistical distribution of the energy levels of classically chaotic systems and the

eigenvalue correlations of random matrix theory, or between the quantum properties of individual deterministically chaotic systems and of ensembles of randomly disordered systems.

Factor 4 (BASINS, ATTRACTORS, INVARIANT SUBSPACE, COUPLED CHAOTIC SYSTEMS, INTERMITTENCY, SYMMETRY BREAKING, MANIFOLDS, also including FRACTALS, SCALING, INVARIANT SETS, GLOBAL DYNAMICS, BIFURCATIONS, PHASE PLANE) – focuses on formation of riddled basins (every point in a chaotic attractor's basin has pieces of another attractor's basin arbitrarily nearby) and off-on intermittency by the loss of transverse stability of an invariant subspace containing a chaotic attractor; examines the effect of perturbation-induced symmetry-breaking on blowout-bifurcations (accompanying Lyapunov exponent sign reversal) that create riddled basins.

Factor 5 (SYNCHRONIZED, FREQUENCY DETUNING, FEEDBACK, COUPLING, LASERS, NOISE, GENERALIZED SYNCHRONIZATION, PHASE LOCKING, COHERENCE RESONANCE, DRIVE SYSTEM, CHUA'S C'RCUIT, LORENZ SYSTEM, INFORMATION SIGNAL, CHAOTIC DYNAMICAL SYSTEMS, also including WEAKLY NONLINEAR ANALYSIS, PATTERN FORMATION, CHAOS, NEURAL NETWORKS, NEURONS, OSCILLATORS) – focuses on synchronization of chaotic dynamical systems, especially optically coupled diode lasers with optical feedback, and examines synchronization robustness with respect to frequency detuning.

Factor 6 (LYAPUNOV EXPONENTS, POWER SPECTRUM, CORRELATION DIMENSIONS, TIME SERIES, KOLMOGOROV ENTROPY, FRACTALS, HEART RATE, SPECTRAL ANALYSIS, CIRCULAR ORBIT, also including ATTRACTORS, INTERMITTENCY, NOISE, CHAOS, POWER LAW, FREQUENCY DOMAIN, TIME DOMAIN, SYSTEM DYNAMICS, POINCARE MAPS, PHASE PLANE, PHASE PORTRAITS) – focuses on application of chaos metrics/ tools (Lyapunov exponents, power spectra, correlation dimension, fractals) to time series, especially from heart and brain wave generators, to fully characterize the nonlinear dynamical components of the signal.

Factor 7 (SCALING, MODULATION EQUATIONS, NORMAL FORMS, PARAMETRIC EXCITATION, LINEAR ANALYSIS, LAGRANGIAN, HOMOCLINIC, FLOQUET THEORY, also including BIFURCATIONS, STABILITY, LIMIT CYCLES, PERIOD DOUBLING, INTERMITTENCY, HOMOCLINIC ORBITS, DUFFING OSCILLATOR) – focuses on use of multiple scales to derive modulation equations (mainly Ginzburg-Landau equations expressing time variation of amplitude and phase), in standard normal form of low co-dimension bifurcations.

Factor 8 (VISCOSITY, WEAKLY NONLINEAR ANALYSIS, FLUID DYNAMICS, SURFACE TENSION, REYNOLDS NUMBERS, ANGULAR VELOCITY, GLOBAL EXISTENCE, PATTERN FORMATION, FREE SURFACE, STEADY-STATE, SHEAR, also including STABILITY, FREQUENCY DETUNING, AMPLITUDE EQUATIONS, FREQUENCY DOMAIN, TIME DOMAIN,) – focuses on dynamics of fluids where

viscosity and surface tension are important (fluid-fluid and fluid-surface interactions, as well as some cases of free-surfaces). Examines stability and pattern formation as functions of different dimensionless parameters (Reynolds Numbers, Weber Number, Bond Number).

Factor 9 (CHAOS, NEURAL NETWORKS, NEURONS, MAPS, COMPLEX SYSTEMS, also including POINCARE MAPS, LIMIT CYCLES, TIME EVOLUTION, STATISTICAL PROPERTIES, ATTRACTORS, SYNCHRONIZED, LORENZ SYSTEM, LYAPUNOV EXPONENTS, CONTROLS, PHASE SPACE, INITIAL CONDITIONS, CHAOTIC DYNAMICS, STATE SPACE, LOCAL DYNAMICS) – focuses on nonlinear dynamics of coupled neurons in complex networks, emphasizing the use of coupled maps exhibiting chaotic oscillations to simulate the network behavior.

Factor 10 (ANGULAR MOMENTUM, TOTAL ENERGY, POWER LAW, NATURAL FREQUENCY, LOCAL MINIMA, FLUCTUATIONS, VORTICITY, also including CLASSICAL SYSTEM, TRACE FORMULA, STATISTICAL PROPERTIES, QUANTUM-CLASSICAL CORRESPONDENCE, TOPOLOGY) – focuses on major integrals of motion of interacting systems described by power law distribution spectra, especially in the transition regime between integrability and chaos.

Factor (EXTERNAL DISTURBANCES, CONTROLS, PARAMETRIC UNCERTAINCIES, SYSTEM RESPONSE, FRICTION, NONLINEAR DYNAMICAL SYSTEMS, MECHANICAL SYSTEMS, DYNAMIC RESPONSE, OPTIMAL CONTROL, NONLINEARITY, CLOSED-LOOP SYSTEM, CONSTANT VELOCITY, RELATIVE DYNAMIC PROPERTIES, also including MODELS, PARAMETERS, NEURAL NETWORKS) - focuses on adaptive robust control of nonlinear dynamical systems subject to external disturbances and parametric uncertainties, with emphasis on mechanical systems such as robots and automobiles.

Factor 12 (HOMOCLINIC ORBITS, PERIODIC ORBITS, TOPOLOGY, PHASE SPACE, SCALAR FIELD, HAMILTONIAN SYSTEMS, CRITICAL POINTS, INITIAL CONDITIONS, ANISOTROPY, VECTOR FIELDS, SINGULARITY, INVARIANT SETS, CHAOTIC DYNAMICS, DUFFING OSCILLATOR, also including POINCARE MAPS, PHASE PLANE, ATTRACTORS, NORMAL FORMS, HOMOCLINIC, MAPS, SYSTEM DYNAMICS) – focuses on orbits for which the stable and unstable manifolds intersect, especially those accompanied at small values of the bifurcation parameter by the existence of a countable set of periodic and an uncountable set of aperiodic solutions (i.e., chaotic structure) in the proximity of the homoclinic.

Factor 13 (DIFFUSION COEFFICIENT, HAUSDORFF DIMENSION, EQUILIBRIUM STATE, RELAXATION, COMPLEX PLANE, LONG-TIME BEHAVIOUR, FIELD LINES, TIME DEPENDENCE, also including EIGENFUNCTIONS, LYAPUNOV EXPONENTS, FRACTALS) – focuses on relations between transport coefficients and chaotic properties for systems relaxing to equilibrium, emphasizing the relation between the diffusion coefficient and the fractality (the Hausdorff Dimension and the Lyapunov exponent) of the hydrodynamic modes of transport.

Factor 14 (EXPONENTIAL DECAY, DECOHERENCE, TOPOLOGICAL ENTROPY, COHERENT STATES, CLOSED ORBITS, ESSENTIAL SPECTRUM, AMPLITUDE EQUATIONS, CONVERGENCE PROPERTIES, PROBABILITY DISTRIBUTIONS, PHASE TRANSITION, also including CLASSICAL SYSTEM, EIGENFUNCTIONS, MUTUAL INFORMATION) –. focuses on decoherence effects of environment and detectors on quantum systems, whose classical correspondents are chaotic, and relates the decay function of the decoherence effect to the purely exponential decay characteristic of chaotic motion.

Factor 15 (ENTROPY, MUTUAL INFORMATION, THERMODYNAMICS, SPEECH, LONG TIME, POPULATION DYNAMICS, CORRELATION FUNCTION, also including QUANTUM MECHANICS, CLASSICAL DYNAMICS, LYAPUNOV EXPONENTS, CORRELATION DIMENSIONS, MAPS, TOPOLOGICAL ENTROPY, QUANTUM DOTS) – focuses on the use of mutual information between random variables and information theory analogues of thermodynamic entropy to analyze system dynamics and time series, in order to indicate structure or correlation and quantify informatioon content.

Factor 16 (FREQUENCY DOMAIN, TIME DOMAIN, DIFFERENTIAL EQUATIONS, FOURIER, SYSTEM DYNAMICS, ASYMPTOTIC EXPANSION, LINEAR SYSTEMS, REAL TIME, PERIODICITY, STATE SPACE, DIFFERENCE EQUATIONS, also including LIMIT CYCLES, FIXED POINTS, COMPLEX BEHAVIOR, TRACE FORMULA, TIME SERIES, CONTROLS, CONVERGENCE PROPERTIES) – focuses on control of limit cycle oscillations in dynamical systems, emphasizing time series analyses (e.g., convolutions) in the time domain, then Fourier transforms of time series into frequency domain, and subsequent frequency domain analyses.

Thus, the 16 factors can be viewed as thrust areas constituting the lowest level taxonomy. Each factor contains one or more of the following elements: 1) Sub-system –specific (e.g., neurons); 2) System-specific (e.g., brain); 3) System-generic (e.g., biological systems); 4) Phenomenon (e.g., bifurcations). Thus, there are myriad ways to combine the factors, depending on which dominant characteristics are chosen. In practice, the aggregation methodology will depend on the application for the taxonomy. For example, if the taxonomy is used to identify participants for a comprehensive workshop on Nonlinear Dynamics sources, categorizing by phenomena would identify e.g., mapping experts, while categorizing by system would identify e.g. laser experts. Selection of aggregation attributes would depend on the workshop objectives. Conversely, assume the taxonomy is used by a program manager to estimate global levels of effort in specific technologies, in order to identify technology areas of adequacy and deficiency. Then, categorizing by phenomena would identify e.g., mapping deficiencies, whereas categorizing by system would identify e.g., laser deficiencies.

The factors above were aggregated by phenomena, using the higher level categorical structuring described in the next section. The following hierarchical level taxonomy resulted (numbers in parenthesis are factor numbers from above).

The highest level taxonomy consists of:

IA-Chaotic Motion

IB-Nonlinear Systems Concepts not necessarily linked to Chaotic Motion

The next highest level taxonomy consists of:

IA1-Characteristics and analysis tools for chaotic systems (1, 3, 4, 6, 12, 13)

IA2-Synchronization and control of coupled systems (5, 9)

1B1-Analytic tools for nonlinear analysis of specific applications (8, 11)

IB2-Methods to simplify solutions of high dimensional nonlinear equations (2, 7, 10, 14, 15, 16)

4.3.1.2.2. Multi-Link Clustering

A symmetrical co-occurrence matrix of the 253 highest frequency high technical content phrases was generated. The matrix elements were normalized using the Equivalence Index (Eij=Cij^2/Ci*Cj, where Ci is the total occurrence frequency of the ith phrase, and Cj is the total occurrence frequency of the jth phrase, for the matrix element ij), and a multi-link clustering analysis was performed using the WINSTAT statistical package. The Average Linkage method was used. Three types of raw data output were generated by each clustering run: a dendogram, a table, and a taxonomy. These three types of data output are described in detail in Appendix 1. The final 253 phrase dendogram is shown in Appendix 8. A description of the final dendogram, and the aggregation of its branches into a taxonomy of categories, follows. The capitalized phrases in parentheses represent cluster boundary phrases for each category.

The 253 phrases in the dendogram are grouped into 26 clusters. These clusters form the lowest level of the taxonomy hierarchy. Each cluster is assigned a letter, ranging from A to Z. The cluster hierarchies are determined by the branch structure. Overall, there are two main branches (clusters). Starting from the phrase adjoining the 'distance' ordinate, the first main cluster (A-M) ranges from MODELS to COMPLEX SYSTEMS. The second main cluster (N-Z) ranges from NONLINEAR PHENOMENA to TIME INTERVALS. While the total dendogram reflects different aspects of nonlinear dynamics, the first cluster (A-M) covers different aspects of chaotic motion, while the second cluster (N-Z) covers nonlinear system concepts with no specified links to chaotic

motion. Each of these large clusters will be divided and sub-divided into smaller clusters, and discussed.

Cluster (A-M) can be divided into clusters (A-I) and (J-M). Cluster (A-I) ranges from MODELS to LINEAR SYSTEMS, and cluster (J-M) ranges from OSCILLATORS to COMPLEX SYSTEMS. Cluster (A-I) focuses on general characteristics of, and tools used to analyze, chaotic systems, while cluster (J-M) focuses on the synchronization and control of coupled systems subject to noise and other external disturbances.

Cluster (N-Z) can be divided into clusters (N-V) and (W-Z). Cluster (N-V) ranges from NONLINEAR PHENOMENA to CHAOTIC INFLATION, and cluster (W-Z) ranges from PERIODIC ORBITS to TIME INTERVALS. Cluster (N-V) focuses on the use of analytical tools (Fokker-Plank equation, Galerkin method, finite element method) for the nonlinear analysis of specific applications (aircraft vorticity, earthquakes, fluid dynamics, speech), and cluster (W-Z) focuses on methods to simplify solutions of high dimensional nonlinear equations (e.g., correspondence of quantum and classical systems, power law approximations, time domain-frequency domain transforms).

Cluster (A-I) can be subdivided into clusters (A-F) and (G-I) Cluster (A-F) ranges from MODELS to SCALAR FIELD, and focuses on analysis tools for, and characteristics of, chaotic systems. Cluster (G-I) ranges from MAPS to LINEAR SYSTEMS, and incorporates phenomena associated with chaotic and non-chaotic systems. Each of these clusters can now be divided into its elemental clusters.

Cluster A (MODELS to LAGRANGIAN) focuses on stability of periodic systems, emphasizing onset and prediction of instabilities; models periodic motions of dynamic systems to identify bifurcations that alter the stability of fixed points into limit cycles; uses multiple scales to derive modulation equations (mainly Ginzburg-Landau equations expressing time variation of amplitude and phase), in standard normal form of low codimension bifurcations.

Cluster B (PERIODIC SOLUTIONS to CONTINUATION METHOD) focuses on stability analysis and routes to chaos, using bifurcation diagrams, reduced and normal forms of the Poincare map, phase portraits, as well as phase plane trajectories to plot the motions.

Cluster C (HOMOCLINIC ORBITS to CIRCULAR ORBITS) focuses on periodic solutions near the homoclinic orbit of the Duffing oscillator with small perturbations, and on the conditions under which chaotic orbits can occur.

Cluster D (CHAOS to MODULATION FREQUENCY) focuses on application of chaos metrics/ tools (Lyapunov exponents, power spectra, correlation dimension, fractals) to time series, especially from heart and brain wave generators, to fully characterize the nonlinear dynamical components of the signal.

Cluster E (ATTRACTORS to COUPLED CHAOTIC SYSTEMS) focuses on formation of riddled basins (every point in a chaotic attractor's basin has pieces of another attractor's basin arbitrarily nearby) and off-on intermittency by the loss of transverse stability of an invariant subspace containing a chaotic attractor; examines the effect of perturbation-induced symmetry-breaking on blowout-bifurcations (accompanying Lyapunov exponent sign reversal) that create riddled basins.

Cluster F (INITIAL CONDITIONS to SCALAR FIELD) focuses on system dynamical evolutions based on initial conditions, and examines the topology of local and global dynamics in the phase space.

Cluster G (MAPS to DYNAMICAL EVOLUTION) focuses on chaotic maps with an invariant measure, the conditions under which period doubling is present on the route to chaos, and the fractality of the chaotic attractor.

Cluster H (DYNAMIC PROPERTIES to STOCHASTIC) focuses on dynamic properties of periodic orbits and chaotic attractors, and includes the use of maps to allow calculations of the location and stabilities of the periodic points in the chaotic attractor.

Cluster I (DIFFERENTIAL EQUATIONS to LINEAR SYSTEMS) focuses on the equations used to describe dynamical systems, and on the parameter-dependent periodic windows in the chaotic motions in which non-chaotic motion may be found.

Cluster (J-M) can be divided into its elemental clusters.

Cluster J (OSCILLATORS to INFORMATION SIGNAL) focuses on synchronization of chaotic dynamical systems, especially optically coupled diode lasers with optical feedback, and examines synchronization robustness with respect to frequency detuning.

Cluster K (SYSTEM DYNAMICS to DETERMINISTIC DYNAMICS) focuses on dynamics of chaotic systems (especially biological) in the presence of noise, including noise-enhanced temporal regularity, leading to determination of the vector field of the chaotic dynamics.

Cluster L (CONTROLS to THEORETICAL MODEL) focuses on adaptive robust control of nonlinear dynamical systems subject to external disturbances and parametric uncertainties, with emphasis on mechanical systems such as robots and automobiles.

Cluster M (NEURAL NETWORKS to COMPLEX SYSTEMS) focuses on use of neural networks to simulate brain subsystems, and the impact of both neuron models and temporal and spatial correlations in neuronal activity on the simulation strength of the neural network.

Cluster (N-V) may be divided into its elemental clusters, and cluster (W-Z) may be divided into its elemental clusters.

Cluster N (NONLINEAR PHENOMENA to ENERGY TRANSFER) focuses on nonlinear phenomena in aircraft flight, such as limit cycle oscillations, and the role of flow-field vortices in these fluid-structure oscillatory phenomena.

Cluster O (QUASIPERIODIC to NORMAL MODES) focuses on solving for velocity distributions and other variables of continuum flows in bounded regions with surface friction, using the Galerkin integral approach to solve the equations; solving for velocity distributions and other variables of particle flows in unbounded regions with interparticle friction, using the Fokker-Planck kinetic equations to solve the equations; solving for structural dynamic responses to relative motions induced by to earthquakes, using finite element techniques.

Cluster P (FLUID DYNAMICS to ESSENTIAL SPECTRUM) focuses on fluid dynamics of partially or fully unbounded flows at different Reynold's Numbers, where surface tension at the free surface tends to increase instabilities and the fluid viscosity tends to reduce instabilities; population dynamics (mainly smaller animal species), emphasizing self-organization and pattern formation.

Cluster Q (IONS to MULTIPLE SOLUTIONS) focuses on quantum dots (semiconductor nanoparticles) and their structural and interaction similarities to large molecules and ions; the use of mutual information between random variables and information theory analogues of thermodynamic entropy to analyze system dynamics and time series, in order to indicate structure or correlation and quantify information content.

Cluster R (CALCULATIONS to NONLINEAR EQUATIONS) focuses on flows in heated channels, and the onset of instabilities as a function of channel aspect ratio and Rayleigh Number.

Cluster S (MAGNETIC FIELDS to LONG-TIME BEHAVIOR) focuses on transport coefficients across and parallel to ambient magnetic field lines in turbulent flows, both in space and fusion-driven plasmas; dissipative fluid flow systems, with turbulent kinetic energy and shear; relations between transport coefficients and chaotic properties for systems relaxing to stationary states, emphasizing the relation between the diffusion coefficient and the fractality (the Hausdorff Dimension and the Lyapunov exponent) of the hydrodynamic modes of diffusion.

Cluster T (STEADY STATE to SPATIAL DISTRIBUTION) focuses on steady-state CO oxidation over Pd or Pt catalysts, including regular, chaotic, or mixed mode reaction rate oscillations driven by mass transfer limitations or external parameter variations.

Cluster U (RESONANCES to CONSTITUTIVE EQUATIONS) focuses on linear approximations to constitutive rheological equations to study temporal evolution of stress and other interface phenomena, emphasizing interface phenomena resonances as a function of parameter variations.

Cluster V (GROUND STATE to CHAOTIC INFLATION) focuses on changes in ordering of layers of molecule-sized particles, as a function of temperature and film thickness; chaotic conditions for chaotic nature of radiation emitted from black hole candidates, and energy spectra of this radiation.

Cluster W (PERIODIC ORBITS to TOTAL ENERGY) focuses on trace formulas, which in general relate the density of states for a given quantum mechanical system to the properties of the periodic orbits of its classical counterpart (quantum-classical correspondence); potential links between the statistical distribution of the energy levels of classically chaotic systems and the eigenvalue correlations of random matrix theory, or between the quantum properties of individual deterministically chaotic systems and of ensembles of randomly disordered systems; major integrals of motion of interacting systems described by power law distribution spectra, especially in the transition regime between integrability and chaos.

Cluster X (BOUNDARY CONDITIONS to DECOHERENCE) focuses on the influence of boundary conditions on the evolution of coherent structures in pattern formation, using the Ginzburg-Landau form of the amplitude equations.

Cluster Y (TIME DOMAIN to OPTIMAL CONTROL) focuses on control of limit cycle oscillations in dynamical systems, emphasizing time series analyses (e.g., convolutions) in the time domain, then Fourier transforms of time series into frequency domain, and subsequent frequency domain analyses; also establishes optimal control conditions for pertubed systems using ergodicity assumptions.

Cluster Z (SYMBOLIC DYNAMICS to TIME INTERVALS) focuses on decoherence effects of environment and detectors on quantum systems, whose classical correspondents are chaotic, and relates the decay function of the decoherence effect to the purely exponential decay characteristic of chaotic motion; use of topological methods to support symbolic dynamics, show existence of closed orbits, and estimate topological entropy.

4.3.1.3. High Frequency Low Frequency Phrase Relationships

The statistical taxonomies were based on symmetrical matrices of relatively high frequency phrases, and the manual taxonomies made some use of mid-frequency phrases. Clustering also allows high frequency phrases to be related to low frequency phrases through the use of symmetric and non-symmetric matrices. The following example is motivated by one of the bibliometrics results.

It was found that China's ranking as a prolific producer of nonlinear dynamics' research papers increased substantially over the past decade. It might be useful to identify their technology focus areas. In particular, it would be interesting to identify some technology areas in nonlinear dynamics in which the U. S. is a major player and China a minor player, and vice versa.

A non-symmetric Abstract phrase-country matrix was generated using the Abstract phrases and countries generated by the ACCESS template. All the countries were included, and Abstract phrases with a frequency of three or greater were included. The matrix elements' values reflected the number of records in which Abstract phrase x co-occurred with country y.

Only the columns for China and the USA were analyzed. The raw data phrases in the China column were normalized (multiplied by approximately three), such that the total number of China's 2001 records was set equal to the total number of USA 2001 records. The phrases in these two columns were compared, and the ratio of record frequencies for China's phrases to those of the USA was used as a comparison metric. This ratio ranged from infinity (finite occurrences in the China column, zero occurrences in the USA column) to zero (zero occurrences in the China column, finite occurrences in the USA column. The number of phrases in the different bands of the comparison metric is shown in Table 11.

TABLE 11 – RATIO OF RECORDS WITH SELECTED PHRASES IN NONLINEAR DYNAMICS CHINA/ USA LITERATURE – 2001

METRIC	
BAND	#
	PHRASES
INFINITY	1238
9 TO 25	138
.11 TO 9	7057
.05 TO .11	34
0	10686

There were a total of 19153 candidate phrases. For the present purpose of identifying major asymmetries, only the phrases with very high or very low record frequency ratios (the wings of the distribution function) were examined. Of this subset, only the phrases above a threshold of record frequencies were considered.

Table 12 contains phrases that met the numeric criteria (above), appeared to be significant technically, and, for the USA-predominant phrases in particular, appeared to be part of a pattern.

TABLE 12 – PHRASES WITH VERY HIGH OR LOW CHINA/ USA RECORD FREQUENCY RATIOS

PHRASE	CHINA RAW- DAT	USA	CHINA NORM	RATIO CH/ US

INTERSTELLAR	0	5	0	0
GALAXY	0	5	0	0

In Table 12, the leftmost column is the phrase of interest, the next column is number of China records in which the phrase appears, the next column is number of USA columns in which the phrase appears, the next column is the normalized China column, and the rightmost column is the ratio of the normalized China column matrix element to the USA column matrix element. The distribution in Table 12, as well as in the raw data, is asymmetric. There are many more phrases that appear predominately in USA records than predominately in China records.

The first six phrases in Table 12 are those that predominate in China records. The only pattern appears to focus on noise. While the phrase NOISE is about equally distributed between China and USA records in the raw data, some variants predominated in the China records, as shown in Table 12.

The remainder of the phrases in Table 12 are those that predominate in USA records. Perhaps the most surprising is MAGNETIC FIELD(S). For the 2001 database, there are 64 USA records that contained MAGNETIC FIELD(S), and no China records. A sampling of these USA records showed them to be of two generic types. The dominant type addressed the nonlinear dynamics of magnetic fields in space plasmas, and the other type addressed the nonlinear dynamics of magnetic fields in controlled magnetic fusion systems. These applications areas require large experimental and flight facilities to conduct research and obtain data. The USA has large efforts in both areas, whereas China has minimal efforts in both. Other USA-dominant phrases from Table 12 relate to space research support this reasoning (SOLAR, GALAXIES, STELLAR, BLACK TROPOSPHERE, GALACTÍC, TELESCOPE, HOLE(S), ASTROPHYSICAL, INTERSTELLAR, GALAXY).

Two major caveats on the data in Table 12 should be emphasized. First, only phrases above the threshold frequency were considered for the candidate phrase pool. Thus, phrases that have zero frequency in Table 12 could in fact have a very low, but finite, frequency. Second, the phrases for the co-occurrence computations were restricted to the Abstracts only. Thus, phrases that occurred in the Keywords or Title were not included.

Other topical areas with patterns of USA predominance include oceanography and weather (SEA, OCEAN, FRONTS, PACIFIC, ICE, EL NINO, MESOSCALE,

SEDIMENT, BAROTROPIC, DEEP WATER, SHALLOW-WATER, WATER DEPTH), aerodynamics (NAVIER-STOKES, VORTICITY, BOUNDARY LAYER, AERODYNAMIC, AIRCRAFT, AEROELASTIC, WIND-TUNNEL, ANGLE OF ATTACK), semiconductors (SEMICONDUCTOR, SEMICONDUCTOR LASER (S)), and encryption (ENCODING, DECODING). In fact, perusal of the lower frequency raw data terms relating to coding shows almost no phrases in any of the variants in the China literature. Again, many of the oceanography/ weather-related papers reflect large-scale experimental programs, from which more data would be available to a developed nation than a developing nation.

Because of the two caveats on the numbers in Table 12 presented previously, the phrases discussed above that reflected areas of USA dominance relative to China were inserted into the SCI, to validate the results. All the fields were examined, with no threshold on phrase frequency. The USA still predominated heavily, by a factor of about five relative to the normalized China frequencies. Thus, the simple method presented here provides the correct order of magnitude answer, but the actual ratio values are overly optimistic. In fact, this combination of using the simple method to identify major technical emphasis differences between countries, followed by a more targeted and detailed analysis of the SCI, is probably a reasonable prototype for a production-level analysis.

While these examples and the associated analysis are very abbreviated due to space limitations, the capability offered is intrinsically very powerful. The high frequency phrase/ low frequency phrase relational technique allows a microcasm of the total text mining study to be performed for any high frequency phrase, or combination of high frequency phrases. When relational indicators are used (not shown in this example), tens, or even hundreds, of low frequency phrases can be identified as relating to a high frequency phrase (depending on the total number of phrases used, and the threshold values of the numerical relational indicators chosen). These low frequency phrases can be categorized into a taxonomy, allowing the technical and bibliometric infrastructure for the high frequency phrase/ concept to be obtained.

4.3.1.4 Recommended Taxonomy

The different statistical and non-statistical taxonomies generated above used different methodologies and some different phrases. Therefore, the results are not directly comparable. A taxonomy that reflects the levels of effort and specific research thrusts would have the structure of the non-statistical Abstract field taxonomy. A taxonomy that reflects commonality of categories would have the structure of the statistical taxonomies.

4.4 Final Observations on Results

This section addresses balance or imbalance of Nonlinear Dynamics with respect to different parameters.

A) Type of Research

In contrast to many of the previous topical text mining studies performed, Nonlinear Dynamics appears to be balanced among theory, experiment, and computational modeling. There is substantial phrase representation in all these research segments.

B) Categories of Research

Compared to most text mining studies performed previously by the first author, Nonlinear Dynamics seems heavily weighted toward basic research. No applied research journals were evident. No companies appeared in the institutional production category, and the only industry appearance was reflected by one of the most cited authors.

However, given the large volume of research activity, the discipline appears poised to transition into applications. There is already ongoing work on antennas, detectors, thermal combustors, and high power lasers that should find its way eventually to industry. The six volumes of experimental papers (not contained in the SCI) from the Proceedings of the Experimental Chaos conference (17-22) provide some indication of the breadth of potential applications.

C) Applications vs Tech Base

There appears to be a reasonable balance between generic tech base studies and more focused areas. Based on the journals and author institutions as stated above, as well as the types of phrases obtained, the focused area studies are more at the basic research level than applied.

Overall, there is a reasonable balance between chaos-oriented phenomena and nonlinear phenomena with no specified links to chaotic motion. Further, there appears to be a reasonable balance among techniques for analyzing chaotic systems, techniques for synchronizing and controlling coupled systems, and use of analytical tools for the nonlinear analysis of specific applications. Progress on methods to simplify solutions of high dimensional nonlinear equations, or on spatio-temporal (infinite dimensional) systems, has been slower.

Within the tech base areas, the priorities seem reasonable. Major emphasis is given to stability and cycling, reasonable emphasis is given to motion, scaling, modeling and simulation, and moderate emphasis is given to communication, control, coupling, thermodynamics, structures, and experiment. Hard divisions among many of these categories are somewhat blurred, because of overlap and potential multiple category assignment of phrases.

Within the focused areas, there is a reasonable balance among physical, environmental, engineering, and life sciences. However, there is a substantial imbalance between the 'hard' and 'soft' sciences. Essentially nothing in the phrase pattern analysis reflected input from the true social and political sciences. The number of articles retrieved from the Social Science Citation Index was four percent of the total articles retrieved. A reading of these 'social science' articles showed that: 1) 'chaos' is

used in the vernacular in a not-insignificant fraction; 2) neuroscience and psychiatry/psychology have reasonable representation, but they were captured in the phrase pattern analysis; 3) there is some effort on financial markets, but too widespread to generate high or mid-frequency phrase outputs; 4) there is minimal effort in the true social and political sciences.

One objective of the present study was to understand the applicability of Nonlinear Dynamics to political trends and predictions. Because chaos applies to deterministic equations, its applications to social systems are problemmatical, since social systems are too noisy to define deterministic trajectories. Too much information is missing in social/ economic systems to model the system accurately enough to find chaos, although other nonlinear responses are apparent. For example, the stock market has dramatic changes, and WWI started over a single assassination.

The documented applications in these social science areas are minimal. There may be a variety of causes in addition to noisy data mentioned above. In the present high tech world economy, both commercial and military, research sponsoring organizations may be far more interested in pursuing 'hard' science applications of Nonlinear Dynamics than 'soft' science applications.

Thus, money for social and political science research in Nonlinear Dynamics may not be available. In addition, because of potential sensitivities of political and social structure dynamics and trends, Nonlinear Dynamics studies may in fact be ongoing, but not published in the open literature. Given the inherent strong feedback and non-linearities in social group situations and organizations at all levels, one would expect that Nonlinear Dynamics could provide useful insights for analyzing and predicting social and political trends.

At a minimum, some of the concepts of Nonlinear Dynamics may be useful to 'softer' science applications, including bifurcations of behaviors, extreme sensitivity to initial conditions, pattern formation, attractors, repellers, and orbits. For example, there is an effort at ONR in war gaming based on cellular automata that has aspects of pattern formation (complexity) arising from simple rules. Flanking maneuvers appear, but have not been explicitly programmed. For all practical purposes, applicability of Nonlinear Dynamics to the 'softer' sciences remains unexplored.

D) Regional

Most previous text mining studies have shown the USA to be dominant in research output, and the Nonlinear Dynamics study is no exception. However, the difference between the USA and the other producers appears to be greater. This imbalance has been reduced over the past decade, from a factor of four greater than its nearest competitor to a factor of three, but it is still substantial. China has ascended as a major competitor, but does not appear to be involved in major areas in which the USA is not working. There is a reasonable balance between Europe and Asia, but still a substantial under-representation from the developing nations.

6. APPENDICES

APPENDIX 1 - CLUSTERING METHODOLOGIES

Phrase clustering is the grouping of word strings by similarity to some metric. When applied to technical literature (unstructured technical text), it produces groups of technical thrusts. The phrase members of each thrust grouping are related to the group's theme. When applied to a bibliometric list, such as a list of technical paper authors, it produces groups of bibliometric quantities (e.g., authors). In the author case, the authors of each group would have some common similarity, depending on the metric chosen. For example, the groups could be defined by people who publish together, or people who work at the same institution, or people who work in the same topical area.

In the present paper, three phrase clustering approaches are used. One approach is non-statistical, and the other two are statistical. Each approach has the same type of starting point. Text to be analyzed is assembled, either from unstructured free text (e.g., reports, databases with free text fields, etc), or databases with bibliometric fields (e.g., databases of journal papers with author name fields, author institution fields, journal fields, etc). The text to be analyzed is then converted to phrases, with a frequency of occurrence associated with each phrase. The physical locations of the phrases in the source documents are retained, so that this co-occurrence information can be exploited in the grouping process. Now, each of the grouping/ clustering methods will be described in detail.

1A. Non-Statistical Clustering

In this paper, TextDicer, successor to the TextSlicer software (associated with the Database Tomography process and system), was used for the non-statistical clustering phrase frequency analysis. This software generates the frequencies of all single and adjacent double and triple (and, recently, quadruple) word high technical content phrases contained in databases of interest. It allows multiple counting of nested phrases (i.e., for the double-word phrase METAL MATRIX, METAL is counted as a single word phrase, MATRIX is counted as a single word phrase, and METAL MATRIX is counted as a double word phrase). Through visual inspection and subsequent manual grouping of the technical phrases by technical experts, taxonomies of each database analyzed are then generated, in order to ascertain the specific technical emphases of each database. Two main criteria are employed to select taxonomy categories. First, the categories should be relatively independent and, in aggregate. should allow for rational allocation of all the phrase frequency data. Second, a balance is required between the unwieldiness of too many categories and the insufficient discrimination of too few categories. To quantify the technical emphases, phrases and their associated frequencies of occurrence are binned into the appropriate taxonomy categories based on the expert analyst's judgement. The frequencies of the phrases in each category are summed to provide some estimate of relative levels of global emphasis of each category.

In the present study, and in all studies that have some specific technical focus, two generic types of high technical content phrases result. One type is application or technology specific (e.g., lasers, fluid turbulence). The other type is applicable to multiple systems or applications (e.g., period doubling, Poincare maps), and is termed tech base phrases. These tech base phrases can be categorized two ways, depending on the taxonomy objectives. One way is to establish general tech base categories (e.g., stability, coupling, scaling, etc), and manually assign these tech base phrases to the appropriate general categories. The other way is to relate the tech base phrases to the more technology or application specific categories, based on the system-specific context in which they were used in the unstructured text. For the latter assignment of tech base phrases into application-specific categories, phrase proximity analysis is required.

For a system or technology-specific technical phrase (e.g., lasers), phrase proximity analysis generates a dictionary of phrases located in close physical proximity to the system-specific phrase throughout the text. Each phrase in the dictionary has a number of associated numerical indicators, including its frequency of occurrence throughout the text. These dictionary phrases are then assigned to the system-specific category in the taxonomy. Depending on the objectives of the study, tech base phrase duplication in categories may be allowed, or adjustments may have to be made across all categories to eliminate phrase duplication (multiple counting).

1B. Statistical Clustering

The statistical clustering approaches start with the phrase frequency and location information, then group phrases based on their co-occurrence frequencies and other important numerical indicators. In this paper, the statistical clustering has used two software packages in tandem. The phrase frequency and location information is generated by TechOasis, a software package from Search Technology. TechOasis uses Natural Language Processing (NLP) to extract the phrases and their frequencies from the free text. Not all phrases are extracted (typical of all NLP), and manual cleanup of the extracted phrases is still required to eliminate the lower technical content phrases. Also, unlike the multiple counting of nested phrases in TextDicer/ TextSlicer, multiple counting of nested phrases in TechOasis is disallowed (i.e., METAL MATRIX would be counted once as a double word phrase, but neither METAL nor MATRIX would be counted as single word phrases). The resulting phrase frequency and cooccurrence matrix information is then exported from TechOasis to WINSTAT, an excellent Excel add-in software package. Two types of output are generated by WINSTAT: factor matrix and multi-link clustering. Each of these processes will now be described.

1B-1. Multi-Link Clustering

Phrase multi-link clustering starts with pre-defined metrics (variables), and groups phrases (cases) based on the strength of their relationships with these metrics. For

example, if a symmetric phrase-phrase matrix is used as the basis for clustering, then the closeness of two phrases (cases) will be determined by their co-occurrence profile with all other phrases (variables). The clustering becomes a co-occurrence profile matching process. The WINSTAT software package produces three types of related outputs.

A dendogram that shows the quantitative linkages among closely-related phrases.
 To provide a different perspective for the reader, an example is taken from a recent study on Electrochemical Power Sources text mining. Figure A1B-1, for example, is a dendogram that portrays linkages among the twenty highest frequency technical content phrases from the Electrochemical Abstracts database.

A dendogram is a tree-like structure that shows linkages among phrases. It does so by starting with a root that encompasses all the phrases (See the vertical line on Figure A1B-1 ranging from a Distance value of 42 to slightly over 40). Then it splits into two groups (clusters) until all the phrases are contained in their own cluster. In Figure A1B-1, the root at the bottom of the page encompasses all the phrases. The first split is into two large clusters. One cluster contains the phrases ELECTROLYTE, CELL, CATHODE, ANODE, and CELLS. The second cluster contains all the remaining phrases LITHIUM, ELECTROCHEMICAL PROPERTIES, CYCLIC VOLTAMMETRY, X-RAY DIFFRACTION, ELECTRODES, ELECTRODE, HYDROGEN, ALLOY, ALLOYS, BATTERY, AIR, OXYGEN, OXIDATION, WATER, and CONDUCTIVITY. The clustering process can be continued at different hierarchical levels.

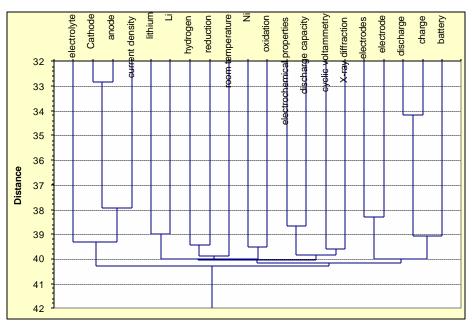

FIGURE A1B-1 – EXAMPLE TWENTY PHRASE DENDOGRAM

Nonlinear Dynamics Text Mining

Appendices

2) A table that contains a quantitative measure of the similarity of adjoining phrases or phrase-cluster pairs. The similarity, or 'distance', is obtained by matching the profiles as described above. Figure A1B-2, for example, is a table that contains the information portrayed in Figure A1B-1. The distances shown on the dendogram are taken from the distances given in this table; thus, the table is the numerical expression of the dendogram.

FIGURE A1B-2 - ELEMENTAL STEPS IN DENDOGRAM FORMATION

Final categories can be generated two ways. The clusters can be manually grouped into categories. Or, the number of categories (clusters) can be specified to the algorithm, and the computer output will contain the final categories. Usually, some modest manual re-grouping of the computer output groups is required to arrive at a final recommended taxonomy.

1C. FACTOR MATRIX CLUSTERING

Factor matrix clustering generates a correlation matrix from the frequency and location information of the phrases. It then generates factors that are composed of all the phrases in the correlation matrix. The phrases are ordered quantitatively by their correlation with each other, with the most strongly correlated assigned the highest quantitative values.

Appendix 3 shows an author factor matrix. The grouping metric was the number of coauthored publications, taking into account the total number of publications of each author. In order to display all factors on one page width, the column widths had to be shrunk drastically. The matrix element values were hidden, but the shadings could be displayed, and they represent high correlation values (factor loadings). The darker the shading, the higher the value.

The number of factors generated can be fully discretionary (e.g., select a ten factor matrix, with no floor on the eigenvalues), or partially discretionary (e.g., set an eigenvalue floor of unity, let the algorithm generate the final number of factors). Final taxonomies can be generated by manually combining factors into categories, or specifying the number of categories (factors) desired to the algorithm.

The author factor matrix in Appendix 3 was generated by selecting an eigenvalue floor of unity. In practice, this means that each factor generated will add new information. Analysis of the author factor matrix in Appendix 3 is performed in the author bibliometrics section of the text, and will not be repeated here.

APPENDIX 2 - MARGINAL UTILITY ALGORITHM

The full 146 term query that was used to retrieve the SCI records for the final iteration (Q1) was:

((CHAO* AND (SYSTEM* OR DYNAMIC* OR PERIODIC* OR NONLINEAR OR NONLINEAR OR BIFURCATION* OR MOTION* OR OSCILLAT* OR CONTROL* OR EQUATION* OR EXPONENT* OR FEEDBACK* OR LYAPUNOV OR MAP* OR ORBIT* OR ALGORITHM* OR HAMILTONIAN OR LIMIT* OR QUANTUM OR RANDOM OR REGIME* OR REGION* OR SERIES OR SIMULATION* OR THEORY OR AMPLITUDE* OR COMMUNICATION* OR COMPLEX* OR CONVECTION OR CORRELATION* OR COUPLING OR CYCLE* OR DEGREES OF FREEDOM OR DETERMINISTIC OR DIFFUSION OR DIMENSION* OR DISTRIBUTION* OR DUFFING OR ENTROPY OR EQUILIBRIUM OR FLUCTUATION* OR FRACTAL* OR

	DOUBLING				

When the query term is a phrase combination, the two columns on the left are the phrases in the combination, and when the query term is a single phrase, the second column from the left is the phrase. The third column from the left is the marginal increase in relevant records retrieved due to the addition of that query term, and the fourth column is the cumulative increase in relevant records. The fifth column represents the cumulative records retrieved divided by the total records retrieved by the full query. The sixth column is the phrase number; the un-truncated query contained 146 terms.

The results indicate a Pareto Law-type phenomenon: Retention of the top 25 query terms (~17%) retrieved about 79% of the records retrieved by the total query. Retention of the top 50 query terms retrieved about 92% of total records, and retention of the top 101 records retrieved 100% of the total. The top 101 terms were selected as the final query, although if query size had been more severely limited, an 80 term query could have been used with perhaps 1.5% less efficiency.

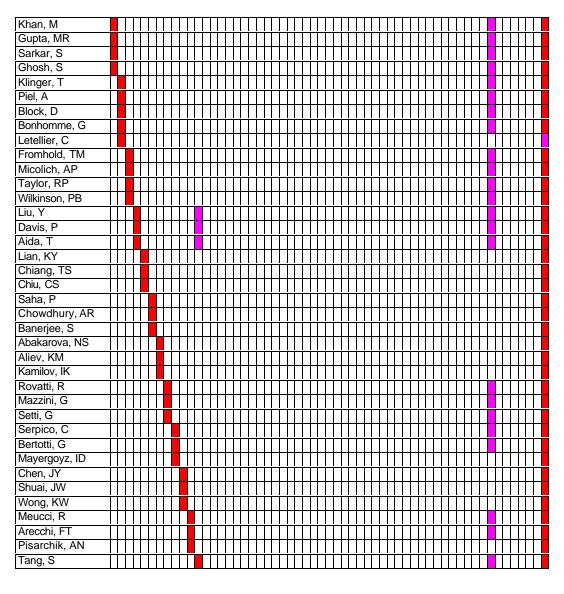

The final query used for the information processing (Q2) is the following:

((CHAO* AND (SYSTEM* OR DYNAMIC* OR PERIODIC* OR NONLINEAR OR BIFURCATION* OR MOTION* OR OSCILLAT* OR CONTROL* OR EQUATION* OR FEEDBACK* OR LYAPUNOV OR MAP* OR ORBIT* OR ALGORITHM* OR HAMILTONIAN OR LIMIT* OR QUANTUM OR REGIME* OR REGION* OR SERIES OR SIMULATION* OR THEORY OR COMMUNICATION* OR COMPLEX* OR CONVECTION OR CORRELATION* OR COUPLING OR CYCLE* OR DETERMINISTIC OR DIMENSION* OR DISTRIBUTION* OR DUFFING OR ENTROPY OR EQUILIBRIUM OR FLUCTUATION* OR FRACTAL* OR INITIAL CONDITION* OR INVARIANT* OR LASER* OR LOGISTIC OR LORENZ OR MAGNETIC FIELD* OR MECHANISM* OR MODES OR NETWORK* OR ONSET OR TIME OR FREQUENC* OR POPULATION* OR STABLE OR ADAPTIVE OR CIRCUIT* OR DISSIPAT* OR EVOLUTION OR EXPERIMENTAL OR GROWTH OR HARMONIC* OR HOMOCLINIC OR INSTABILIT* OR OPTICAL)) OR (BIFURCATION* AND (NONLINEAR OR HOMOCLINIC OR QUASIPERIODIC OR QUASI-PERIODIC OR DOUBLING OR DYNAMICAL SYSTEM* OR EVOLUTION OR INSTABILIT* OR SADDLE-NODE* OR MOTION* OR OSCILLAT* OR TRANSCRITICAL OR BISTABILITY OR LIMIT CYCLE* OR POINCARE OR LYAPUNOV OR ORBIT*)) OR (NONLINEAR AND (PERIODIC SOLUTION* OR OSCILLAT* OR MOTION* OR HOMOCLINIC)) OR (DYNAMICAL SYSTEM* AND (NONLINEAR OR STOCHASTIC OR NON-LINEAR)) OR ATTRACTOR* OR PERIOD DOUBLING* OR CORRELATION DIMENSION* OR

APPENDIX 7 - ABSTRACT PHRASE CONSOLIDATION FOR STATISTICAL CLUSTERING

This Appendix describes the process used to consolidate the phrases generated by the TechOasis Natural Language Processor into phrases input to the statistical clustering algorithms. Because the WINSTAT clustering package used is an Excel add-in, the number of phrases that can be selected for statistical clustering is subject to the Excel column limit of ~250. In order to utilize the maximum available information, similar

phrases are consolidated, thereby allowing a larger number of phenomena to be clustered.

The highest frequency high technical content phrases output by the Techoasis Natural Language Processor were selected. No phrases below a threshold frequency of seven were selected from these TechOasis output phrases. Table A7-1 shows the 640 preconsolidation phrases selected initially. The first column is the record frequency (the number of Abstracts that contain the phrase), the second column is the phrase, and the third column is the consolidation parameter. Phrases to be consolidated were assigned the same number in the third column. Each group of combined phrases was 'umbrellad' under typically the most generic phrase in the group. The 640 phrases in Table A7-1 were consolidated into 253 phrases, and inserted into the WINSTAT clustering algorithms for both the factor matrix and multi-link clustering analyses.
